Let's play a game

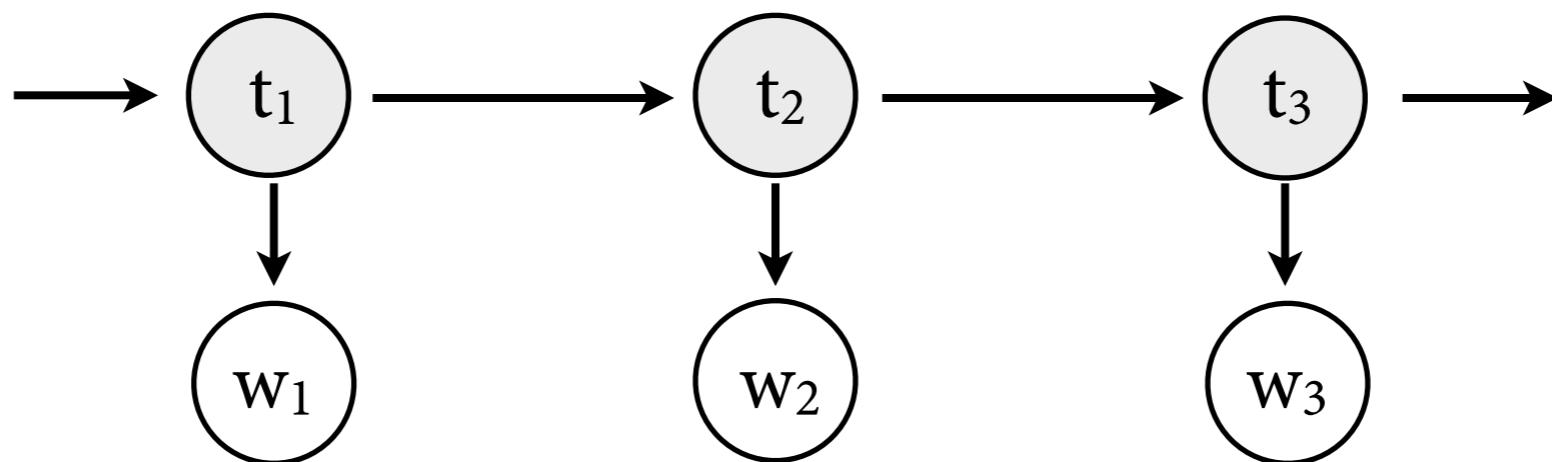

- I will write a sequence of part-of-speech tags and of words on the board.
- You take turns in giving me POS tags and words, and I will write them down.

Penn Treebank POS tags

Tag	Description	Example	Tag	Description	Example
CC	Coordin. Conjunction <i>and, but, or</i>		SYM	Symbol	+,%,&
CD	Cardinal number	<i>one, two, three</i>	TO	“to”	<i>to</i>
DT	Determiner	<i>a, the</i>	UH	Interjection	<i>ah, oops</i>
EX	Existential ‘there’	<i>there</i>	VB	Verb, base form	<i>eat</i>
FW	Foreign word	<i>mea culpa</i>	VBD	Verb, past tense	<i>ate</i>
IN	Preposition/sub-conj	<i>of, in, by</i>	VBG	Verb, gerund	<i>eating</i>
JJ	Adjective	<i>yellow</i>	VBN	Verb, past participle	<i>eaten</i>
JJR	Adj., comparative	<i>bigger</i>	VBP	Verb, non-3sg pres	<i>eat</i>
JJS	Adj., superlative	<i>wildest</i>	VBZ	Verb, 3sg pres	<i>eats</i>
LS	List item marker	<i>1, 2, One</i>	WDT	Wh-determiner	<i>which, that</i>
MD	Modal	<i>can, should</i>	WP	Wh-pronoun	<i>what, who</i>
NN	Noun, sing. or mass	<i>llama</i>	WP\$	Possessive wh-	<i>whose</i>
NNS	Noun, plural	<i>llamas</i>	WRB	Wh-adverb	<i>how, where</i>
NNP	Proper noun, singular	<i>IBM</i>	\$	Dollar sign	\$
NNPS	Proper noun, plural	<i>Carolinas</i>	#	Pound sign	#
PDT	Predeterminer	<i>all, both</i>	“	Left quote	(‘ or “)
POS	Possessive ending	<i>'s</i>	”	Right quote	(' or ”)
PP	Personal pronoun	<i>I, you, he</i>	(Left parenthesis	([, (, {, <)
PP\$	Possessive pronoun	<i>your, one's</i>)	Right parenthesis	(],), }, >)
RB	Adverb	<i>quickly, never</i>	,	Comma	,
RBR	Adverb, comparative	<i>faster</i>	.	Sentence-final punc	(. ! ?)
RBS	Adverb, superlative	<i>fastest</i>	:	Mid-sentence punc	(: ; ... - -)
RP	Particle	<i>up, off</i>			

Hidden Markov Models

- Last week's generative story: generate words at random from n-gram model $P(w_n \mid w_1, \dots, w_{n-1})$.
- Replace with new generative story:
 - Language is generated by a two-step process.
 - First, generate sequence of hidden POS tags t_1, \dots, t_T tag by tag, left to right from bigram model $P(t_i \mid t_{i-1})$.
 - Independently, generate an observable word w_i from each t_i , at random from model $P(w_i \mid t_i)$.

Question 1: Language modeling

- Given an HMM and a string w_1, \dots, w_T , what is the likelihood $P(w_1 \dots w_T)$?
- We can compute $P(w_1 \dots w_T)$ efficiently with the *forward algorithm*.

DT NN VBD NNS IN DT NN

DT JJ NN VBZ IN DT NN

The representative put chairs on the table. p_2

$$P(\text{sentence}) = p_1 + p_2$$

Question 2: Tagging (aka Decoding)

- Given an HMM and an observed string w_1, \dots, w_T , what is the most likely sequence of hidden tags t_1, \dots, t_T ?
- We can compute $\arg \max_{t_1, \dots, t_T} P(t_1, w_1, \dots, t_T, w_T)$ efficiently with the *Viterbi algorithm*.

Question 3a: Supervised learning

- Given a set of POS tags and *annotated* training data $(w_1, t_1), \dots, (w_T, t_T)$, compute parameters for HMM that maximize likelihood of training data.
- Do it efficiently with maximum likelihood training plus smoothing.

DT NN VBD NNS IN DT NN

Secretariat is expected to race tomorrow.

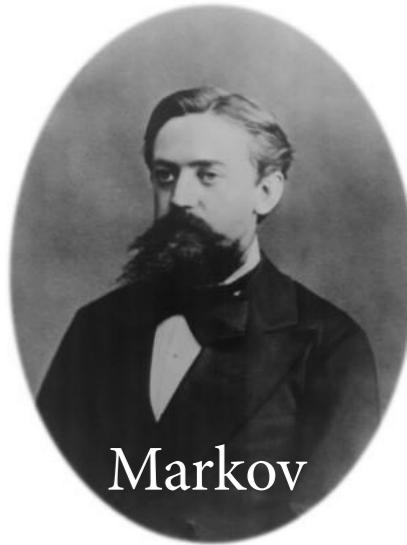

Question 3b: Unsupervised learning

- Given a set of POS tags and *unannotated* training data w_1, \dots, w_T , compute parameters for HMM that maximize likelihood of training data.
- Do it with the *forward-backward algorithm* (an instance of *Expectation Maximization*).

The representative put chairs on the table.

Secretariat is expected to race tomorrow.

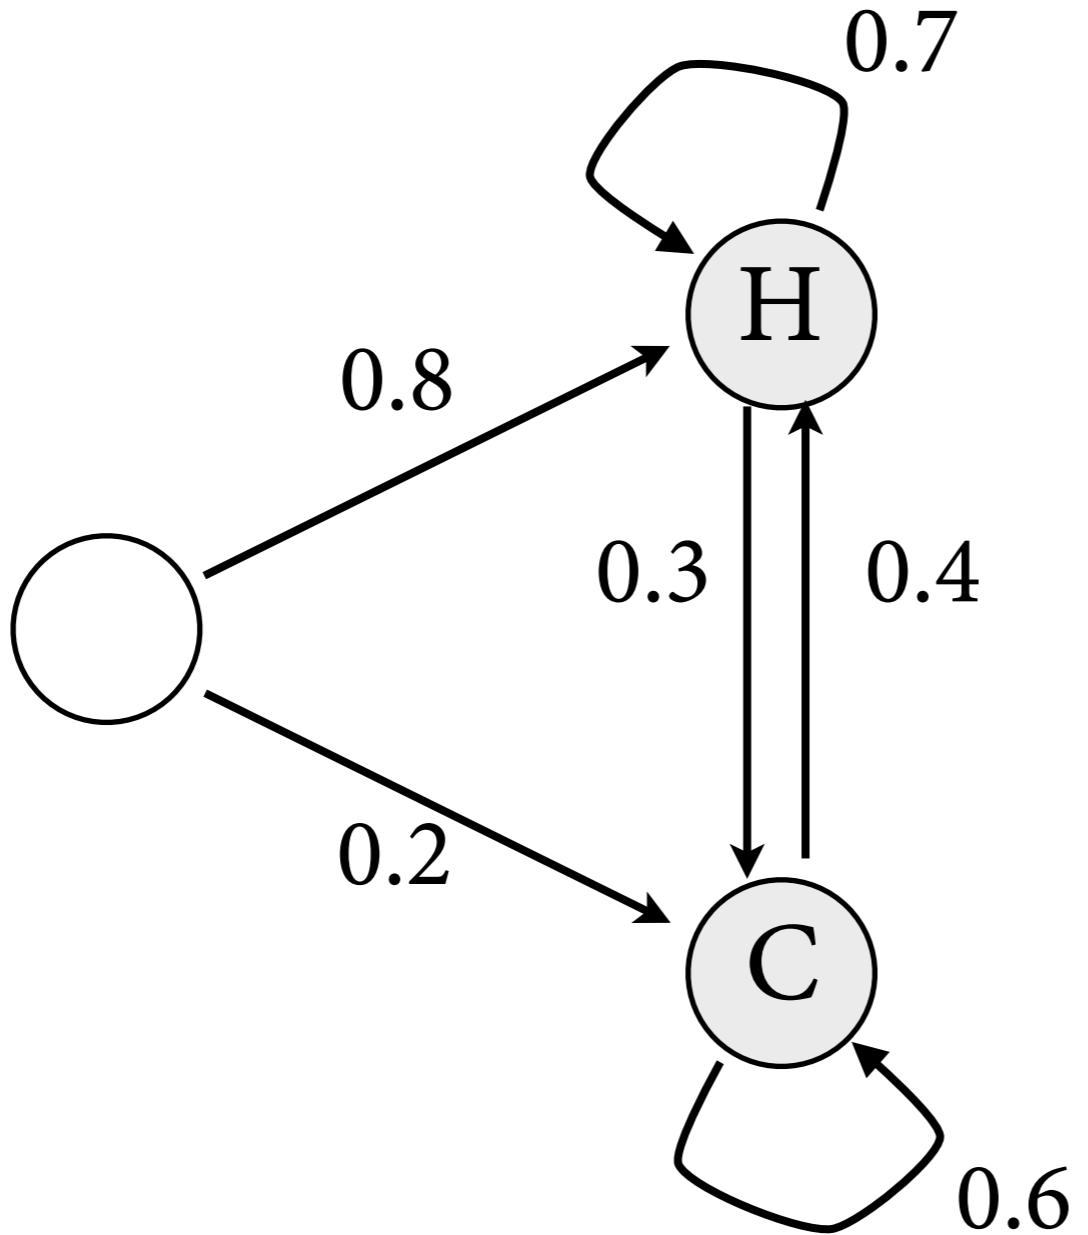

Hidden Markov Models

Markov

- A *Hidden Markov Model* is 5-tuple consisting of
 - ▶ finite set $Q = \{q_1, \dots, q_N\}$ of *states* (= POS tags)
 - ▶ finite set O of possible *observations* (= words)
 - ▶ *transition probabilities* $a_{ij} = P(X_{t+1} = q_j \mid X_t = q_i)$
$$\sum_{j=1}^N a_{ij} = 1$$
 - ▶ *initial probabilities* $a_{0i} = P(X_1 = q_i)$
$$\sum_{i=1}^N a_{0i} = 1$$
 - ▶ *emission probabilities* $b_i(o) = P(Y_t = o \mid X_t = q_i)$
$$\sum_{o \in O} b_i(o) = 1$$
- The HMM describes two coupled random processes:
 - ▶ event $X_t = q_i$: At time t, HMM is in state q_i .
 - ▶ event $Y_t = o$: At time t, HMM emits observation o .

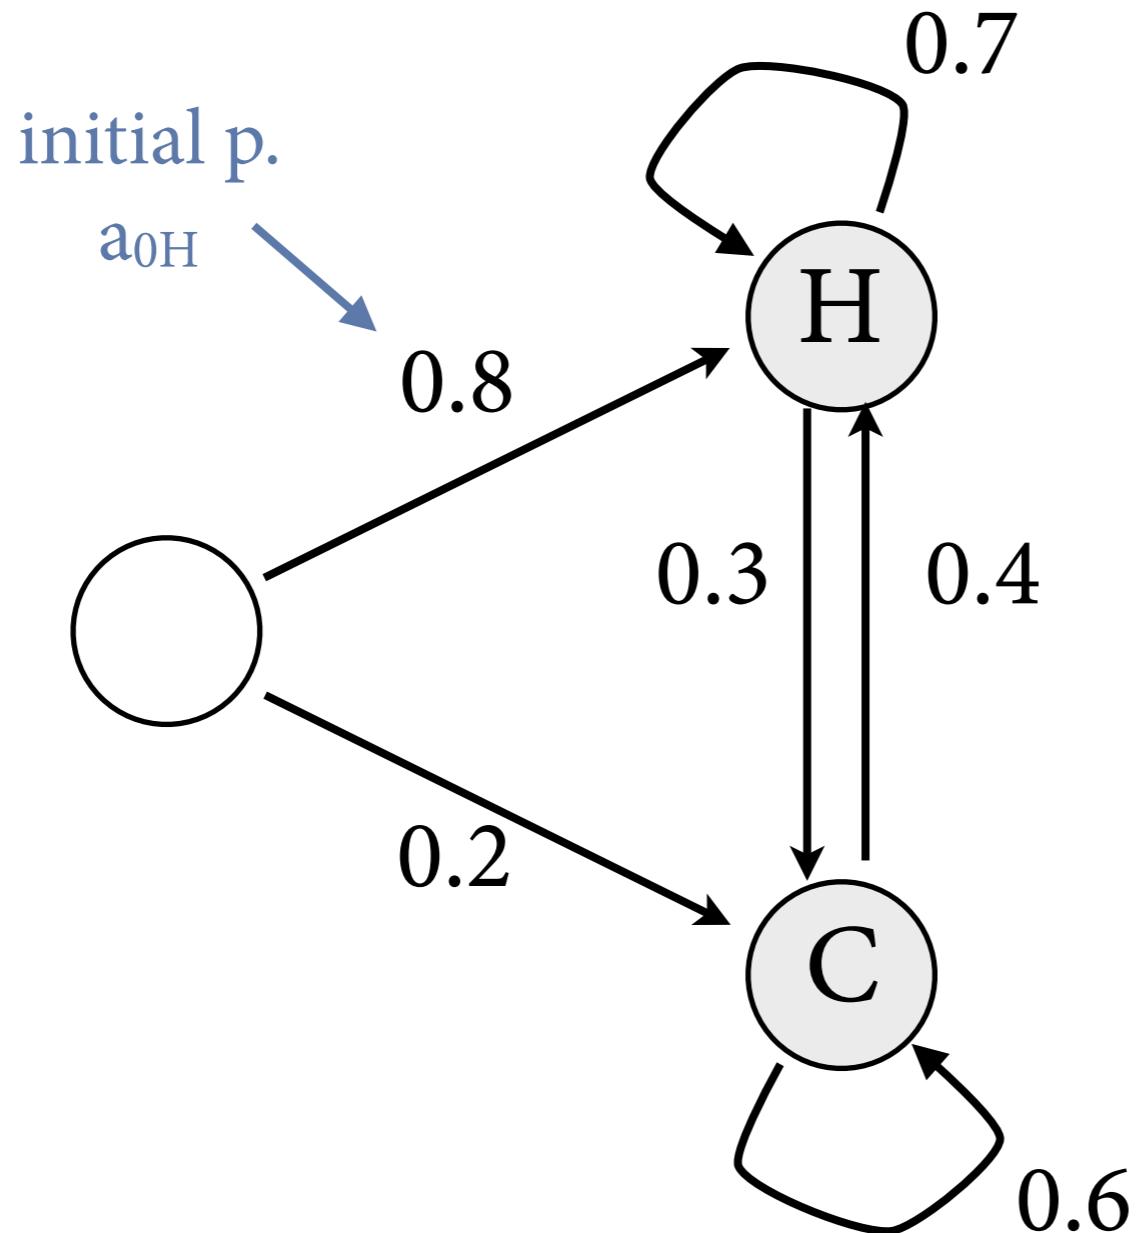

Example: Eisner's Ice Cream

States represent weather on a given day: Hot, Cold

Outputs represent number of ice creams Jason eats that day

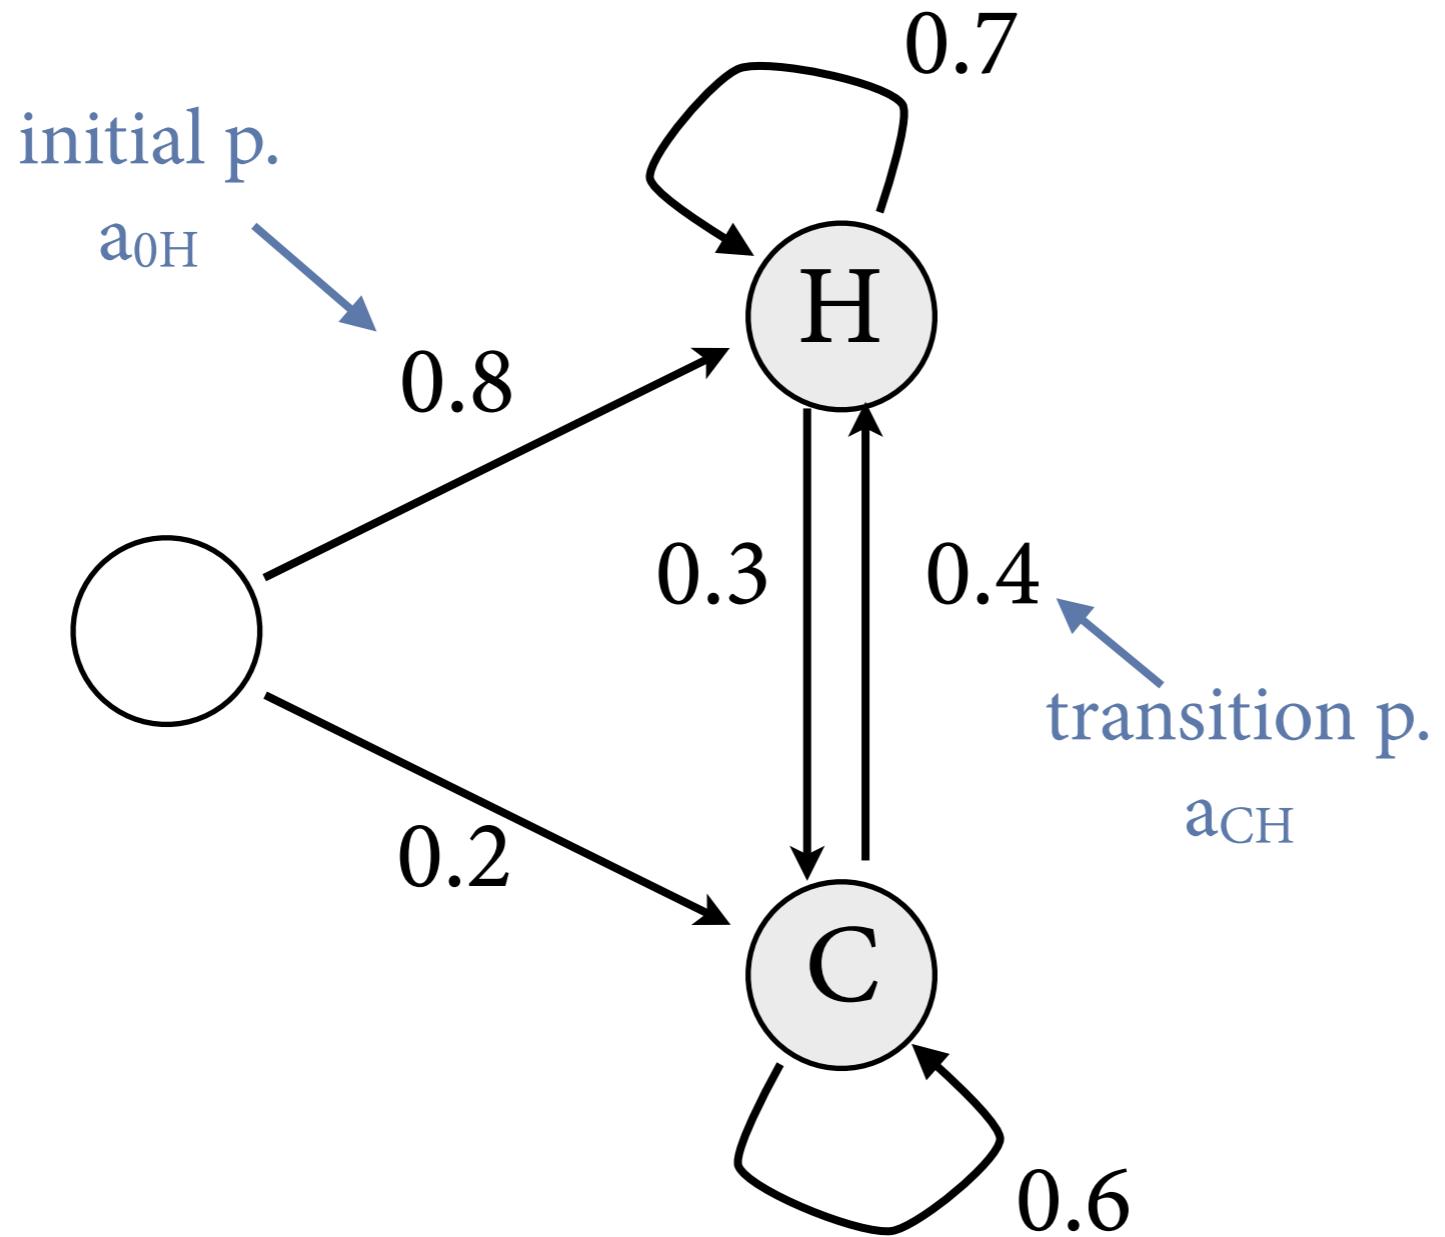

Example: Eisner's Ice Cream

States represent weather on a given day: Hot, Cold

Outputs represent number of ice creams Jason eats that day

Outputs represent number of ice creams Jason eats that day

Example: Eisner's Ice Cream

States represent weather on a given day: Hot, Cold

Outputs represent number of ice creams Jason eats that day

HMMs joint model of x, y

- Coupled random processes of HMM directly give us model for *joint* probability $P(x, y)$ where
 - ▶ $y = y_1 \dots y_T$ sequence of observations
 - ▶ $x = x_1 \dots x_T$ sequence of hidden states
- Defined as follows:

$$P(x, y) = P(x) \cdot P(y | x)$$

$$= \prod_{t=1}^T P(X_t = x_t | X_{t-1} = x_{t-1}) \cdot \prod_{t=1}^T P(Y_t = y_t | X_t = x_t)$$

$$= \prod_{t=1}^T a_{x_{t-1} x_t} \cdot \prod_{t=1}^T b_{x_t}(y_t)$$

Question 2: Tagging

- Given observations y_1, \dots, y_T (# ice creams), what is the most probable sequence x_1, \dots, x_T of hidden states (temperatures)?
- Maximum probability:

$$\max_{x_1, \dots, x_T} P(x_1, \dots, x_T \mid y_1, \dots, y_T)$$

- We are primarily interested in $\arg \max$:

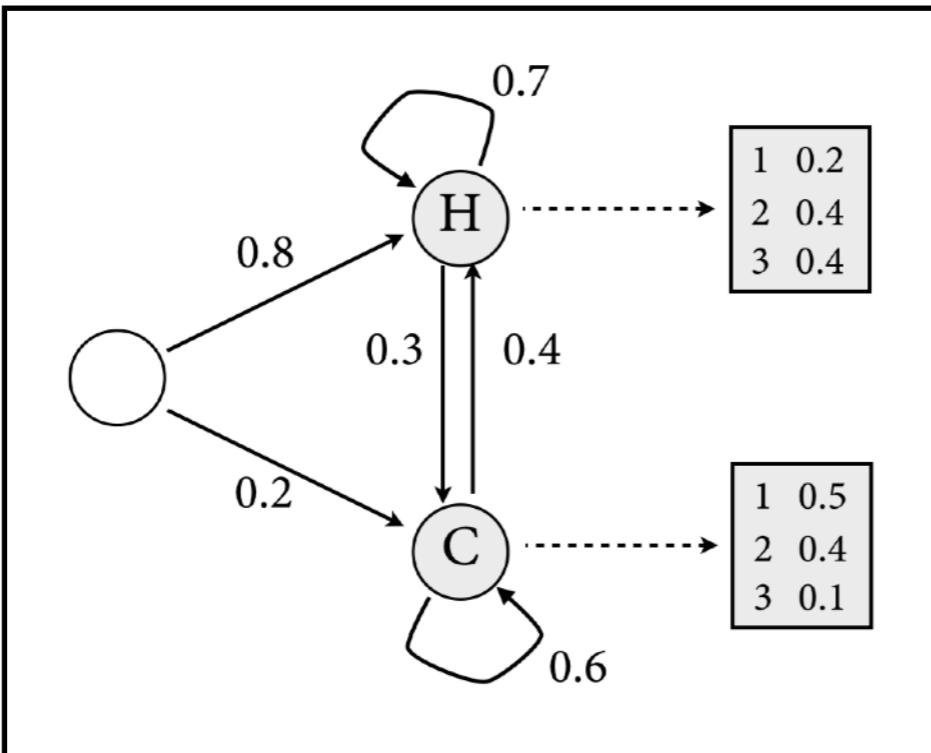

$$\arg \max_{x_1, \dots, x_T} P(x_1, \dots, x_T \mid y_1, \dots, y_T)$$

$$= \arg \max_{x_1, \dots, x_T} \frac{P(x_1, \dots, x_T, y_1, \dots, y_T)}{P(y_1, \dots, y_T)}$$

$$= \arg \max_{x_1, \dots, x_T} P(x_1, \dots, x_T, y_1, \dots, y_T)$$

Naive approach

- Let's say Jason ate 3, 1, 3 ice creams. What was the most likely weather on these three days?
- Compute $\max P(x_1, 3, x_2, 1, x_3, 3)$ by maximizing over all possible state sequences.

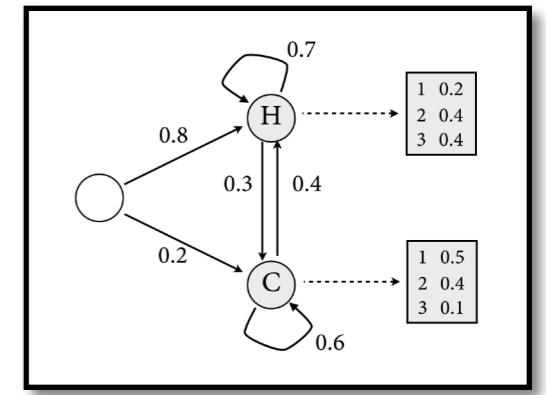

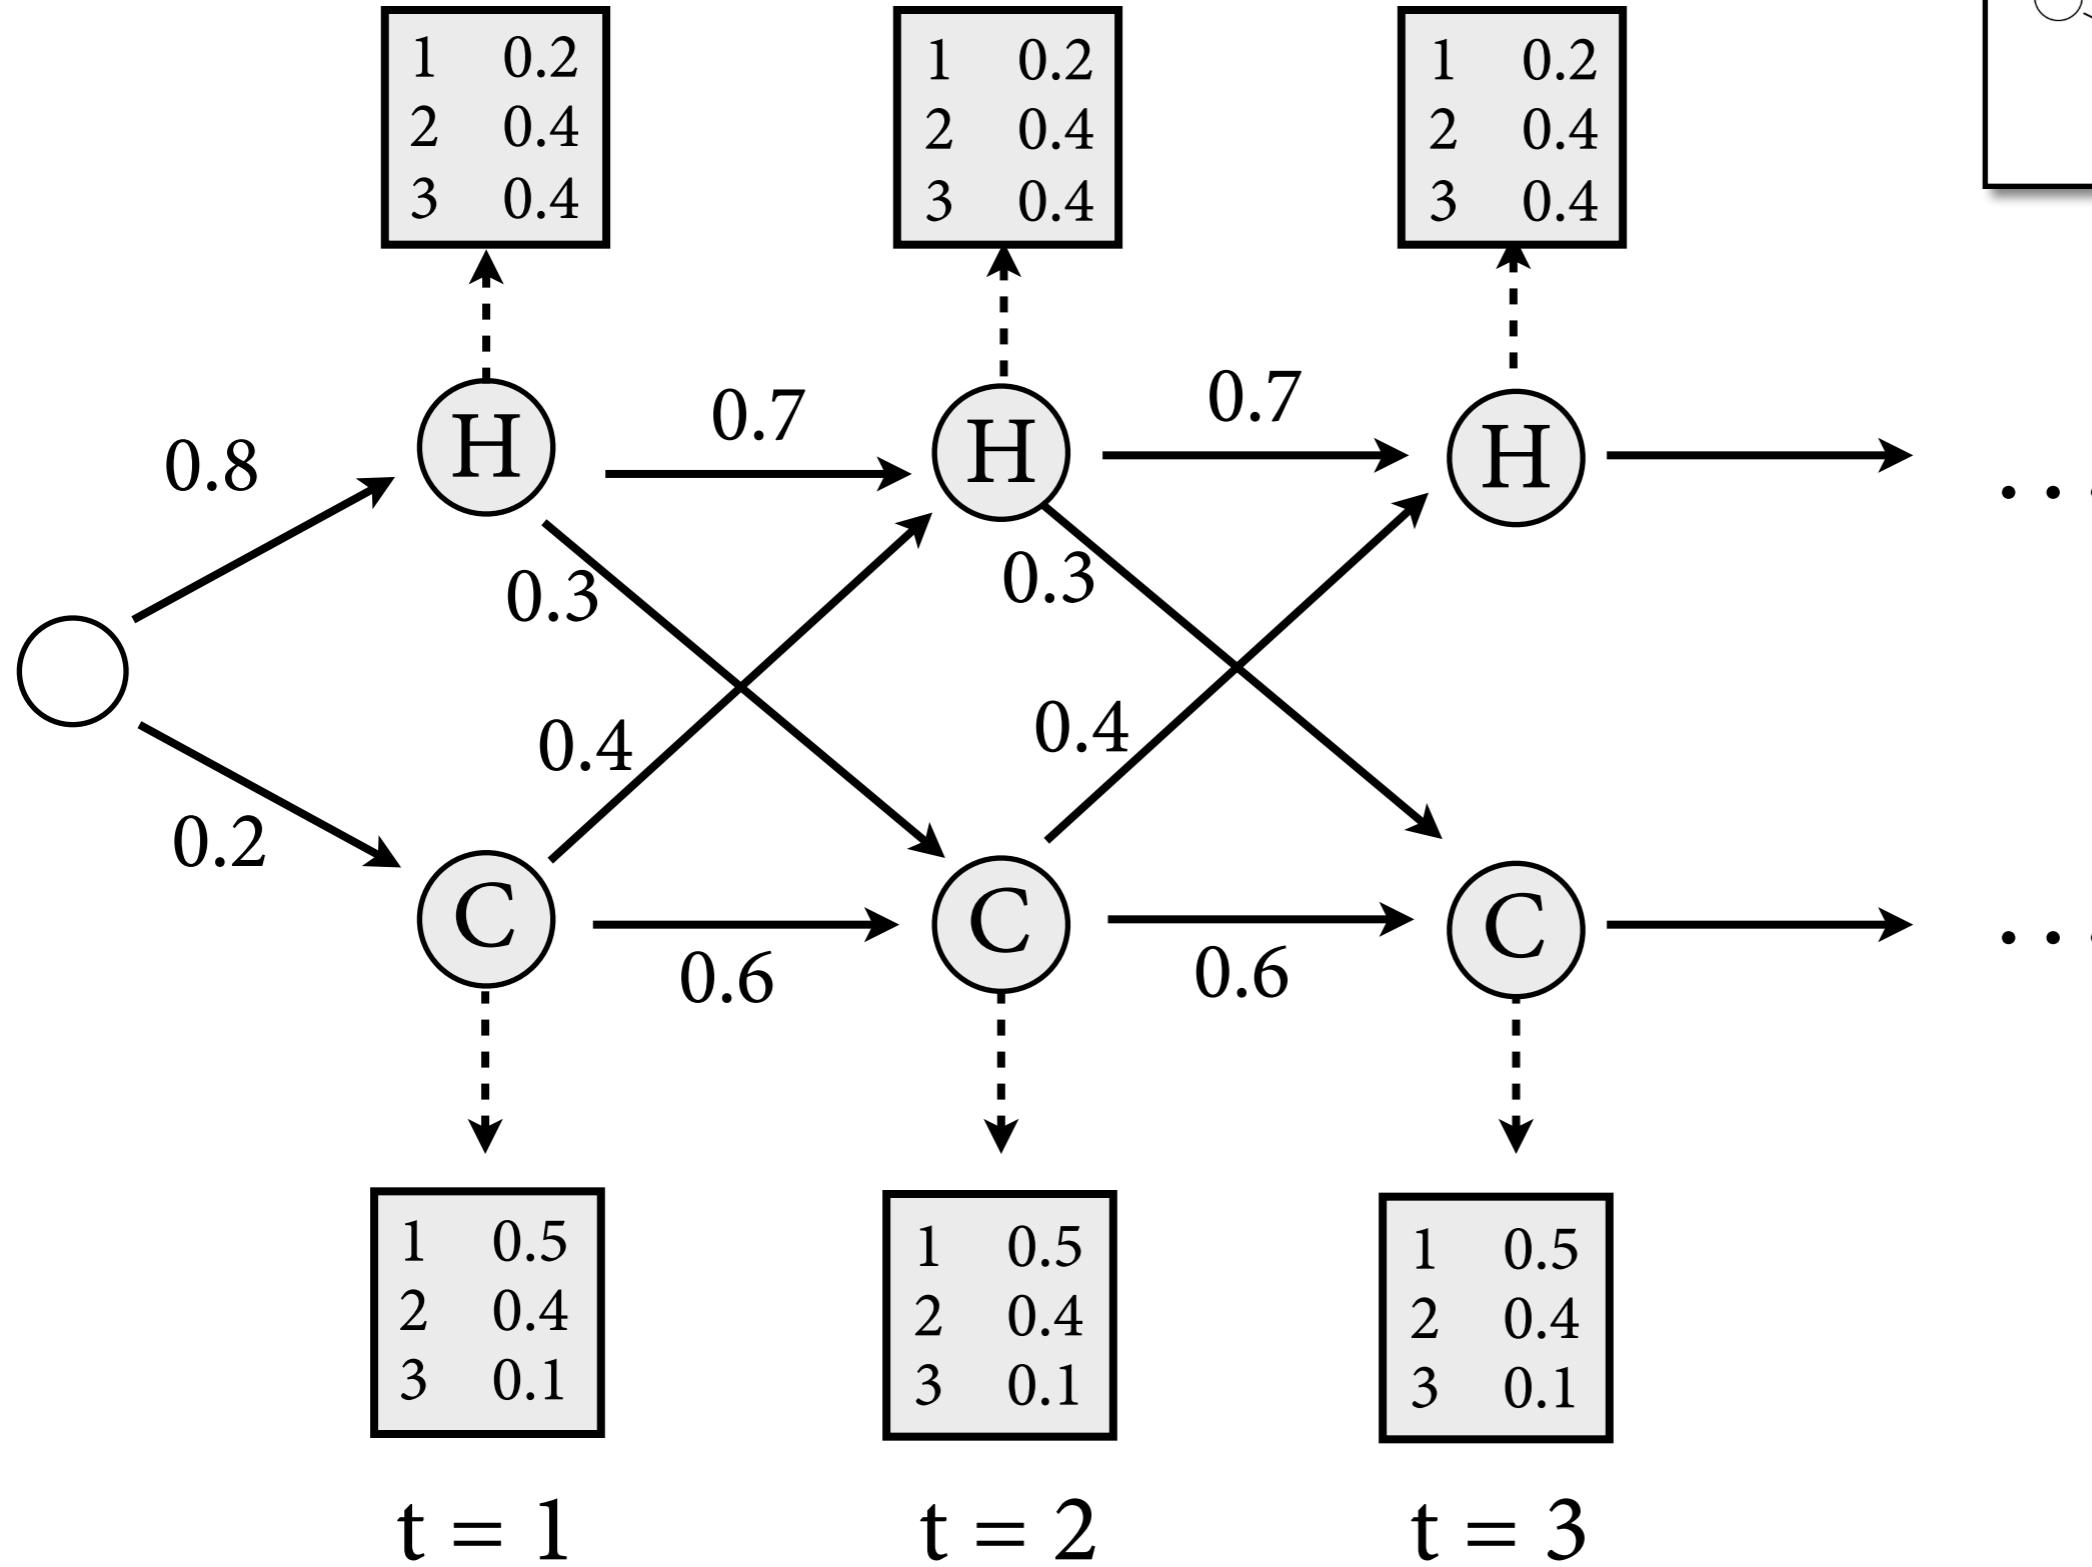

$P(x_1, 3, x_2, 1, x_3, 3)$ is max of	
$P(H, 3, H, 1, H, 3)$	0.012
$P(H, 3, H, 1, C, 3)$	0.001
$P(H, 3, C, 1, H, 3)$	0.008
...	...
<u>$P(C, 3, C, 1, C, 3)$</u>	<u>0.0004</u>
	= 0.012

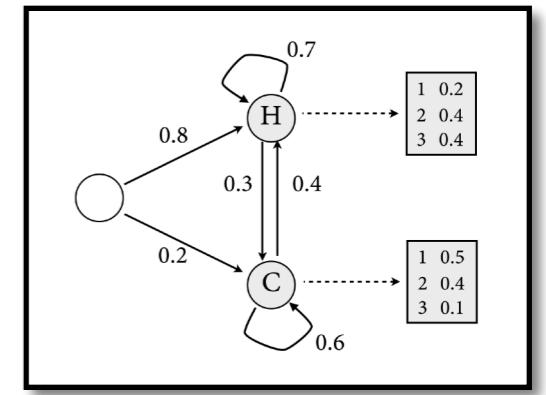

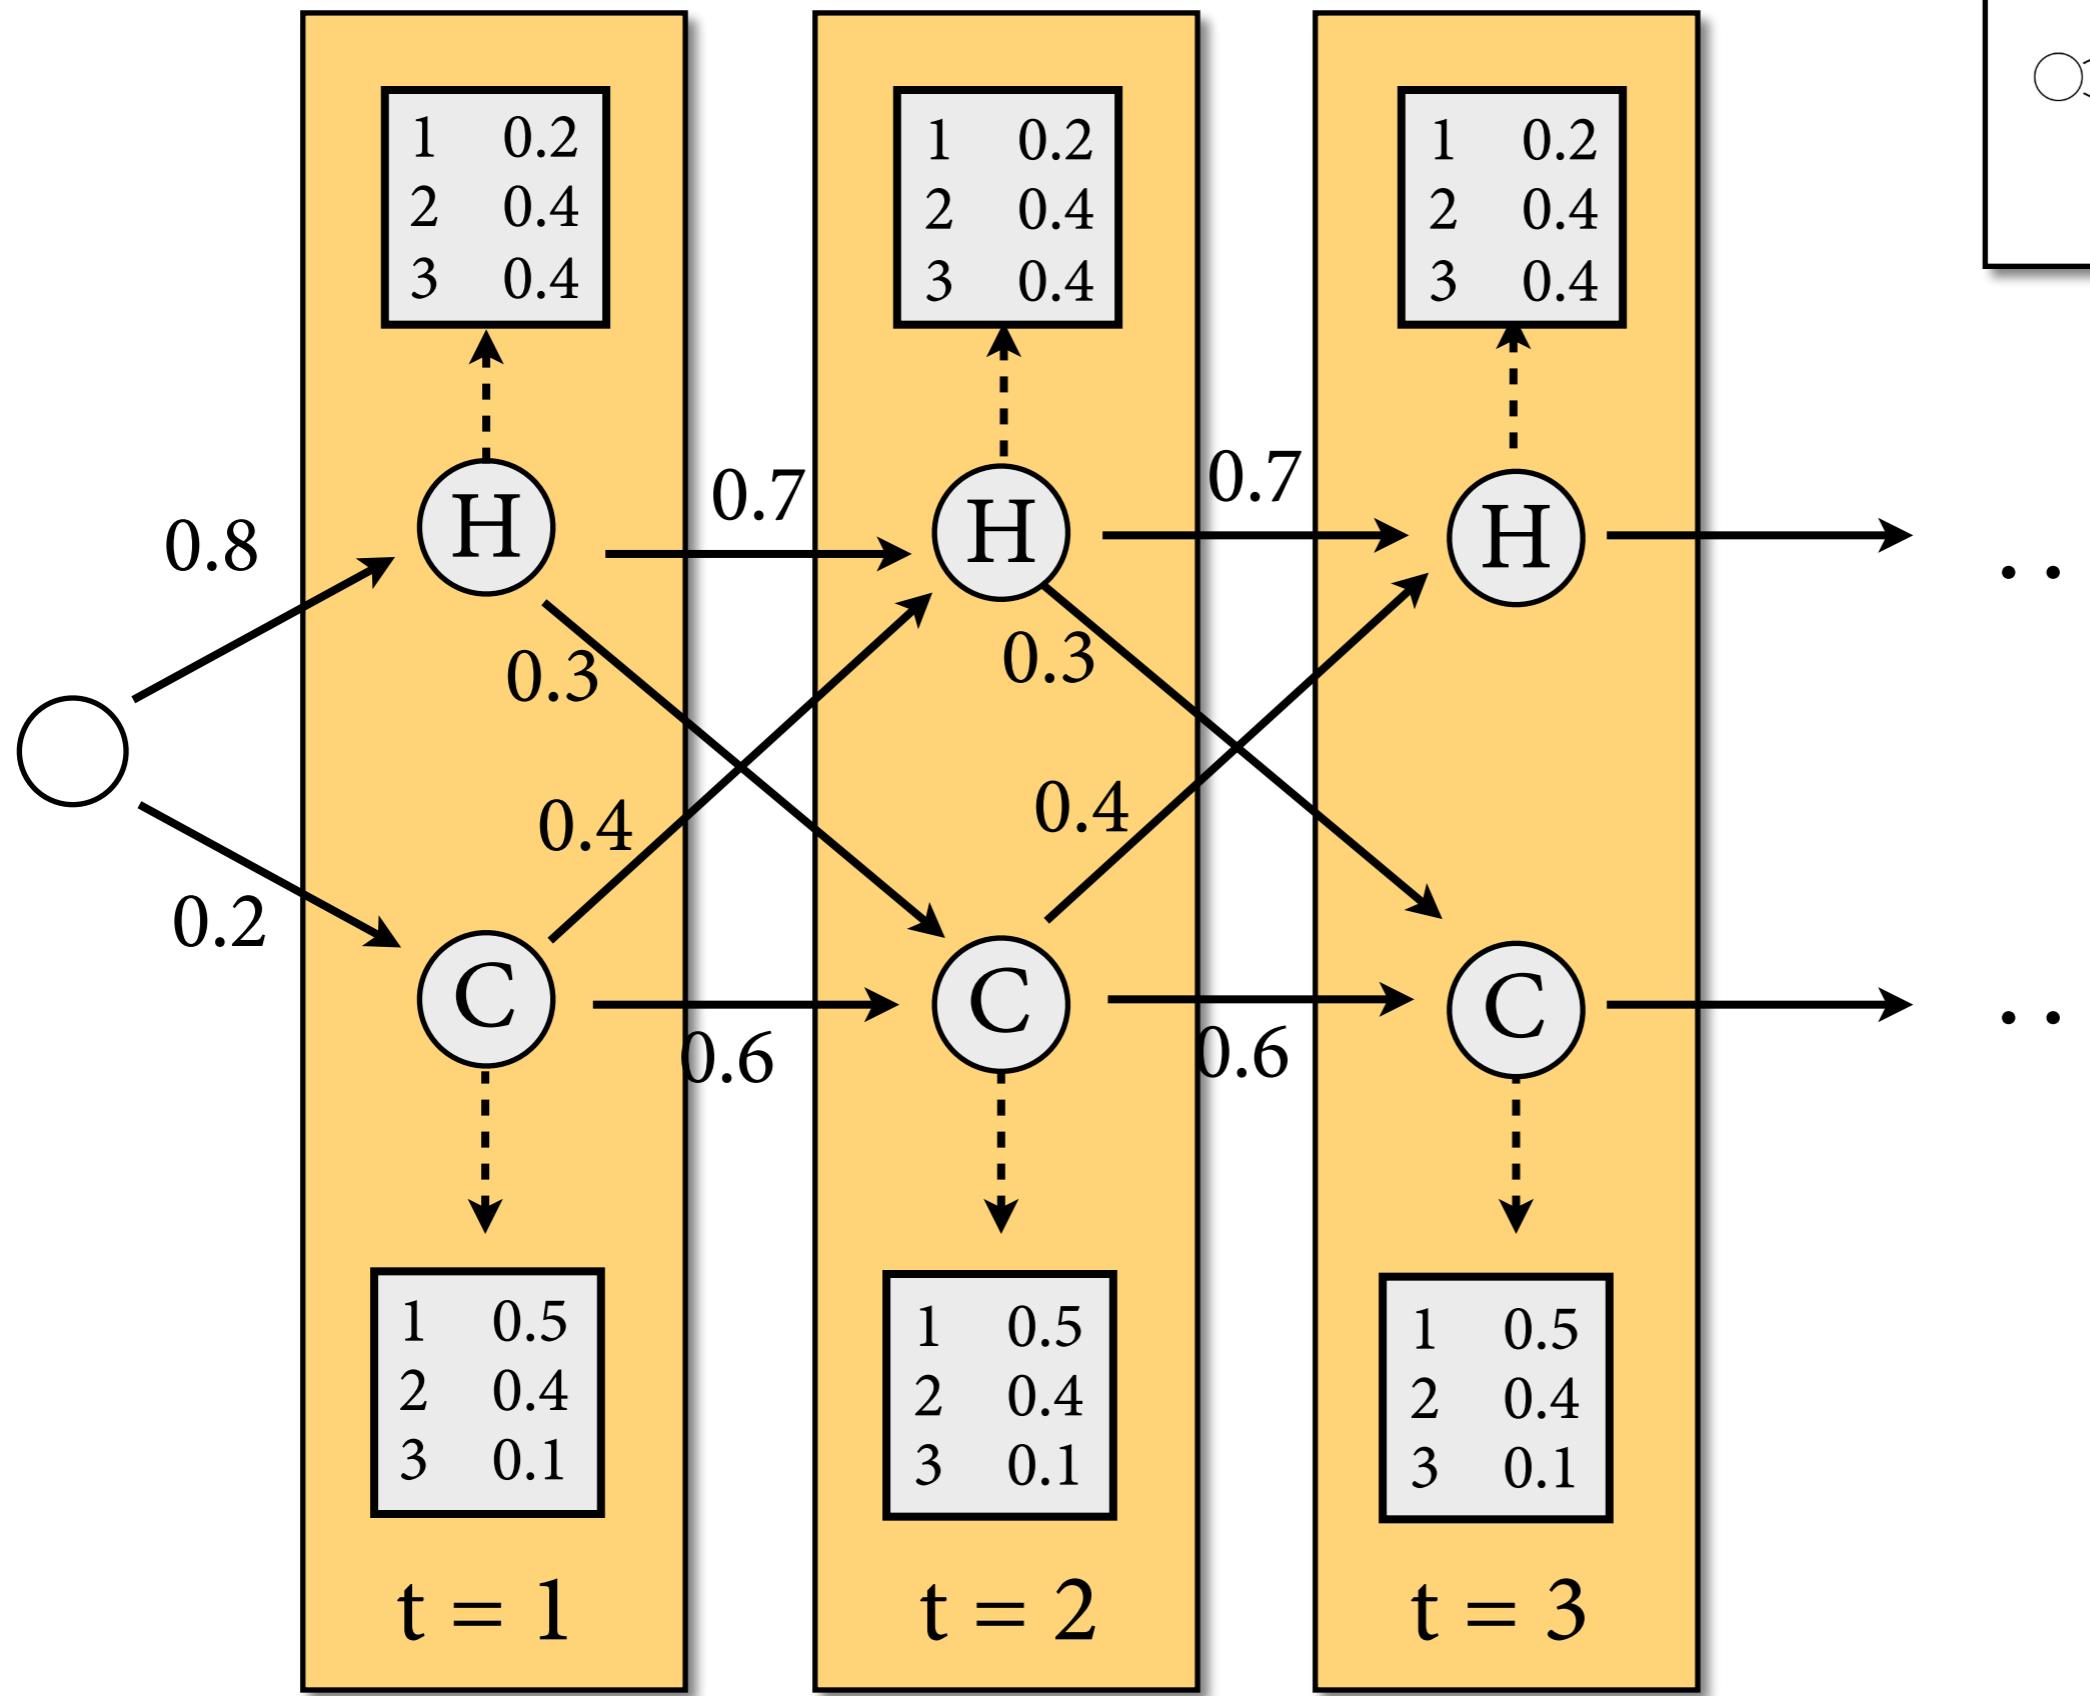

Too expensive

- Naive approach maximizes over exponential set of terms. This is too slow for practical use.
- Visualize this in *trellis*: unfolding of HMM
 - ▶ one column for each time point t , represents X_t
 - ▶ each column contains a copy of each state of HMM
 - ▶ edges from t to $t+1$ = transitions of HMM
- Each path through trellis represents one state sequence.
 - ▶ So computation of $\max P(x,y) = \max$ over all paths.

The Viterbi Algorithm

- Because of statistical independencies, can decompose joint probability:

$$\begin{aligned} P(x_1, y_1, \dots, x_t, y_t) &= P(y_t \mid x_1, \dots, x_t, y_1, \dots, y_{t-1}) \cdot P(x_t \mid x_1, \dots, x_{t-1}, y_1, \dots, y_{t-1}) \\ &\quad \cdot P(x_1, y_1, \dots, x_{t-1}, y_{t-1}) \\ &= P(y_t \mid x_t) \cdot P(x_t \mid x_{t-1}) \cdot P(x_1, y_1, \dots, x_{t-1}, y_{t-1}) \end{aligned}$$

- Thus, maximum has recursive structure:

$$\begin{aligned} V_t(j) &= \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j) \\ &= \max_{x_1, \dots, x_{t-1}} P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid x_{t-1}) \cdot P(y_1, \dots, y_{t-1}, x_1, \dots, x_{t-1}) \\ &= \max_{x_{t-1}} P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid x_{t-1}) \cdot (\max_{x_1, \dots, x_{t-2}} P(y_1, \dots, y_{t-1}, x_1, \dots, x_{t-1})) \\ &= \max_i P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid X_{t-1} = q_i) \cdot (\max_{x_1, \dots, x_{t-2}} P(y_1, \dots, y_{t-1}, x_1, \dots, X_{t-1} = q_i)) \\ &= \max_i P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid X_{t-1} = q_i) \cdot V_{t-1}(i) \end{aligned}$$

The Viterbi Algorithm

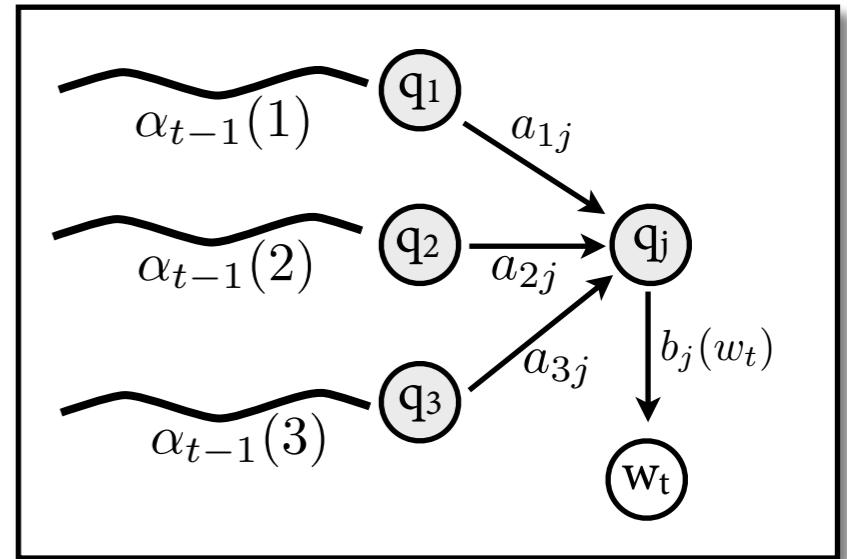

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

- Base case, $t = 1$:

$$V_1(j) = b_j(y_1) \cdot a_{0j}$$

- Inductive case, for $t = 2, \dots, T$:

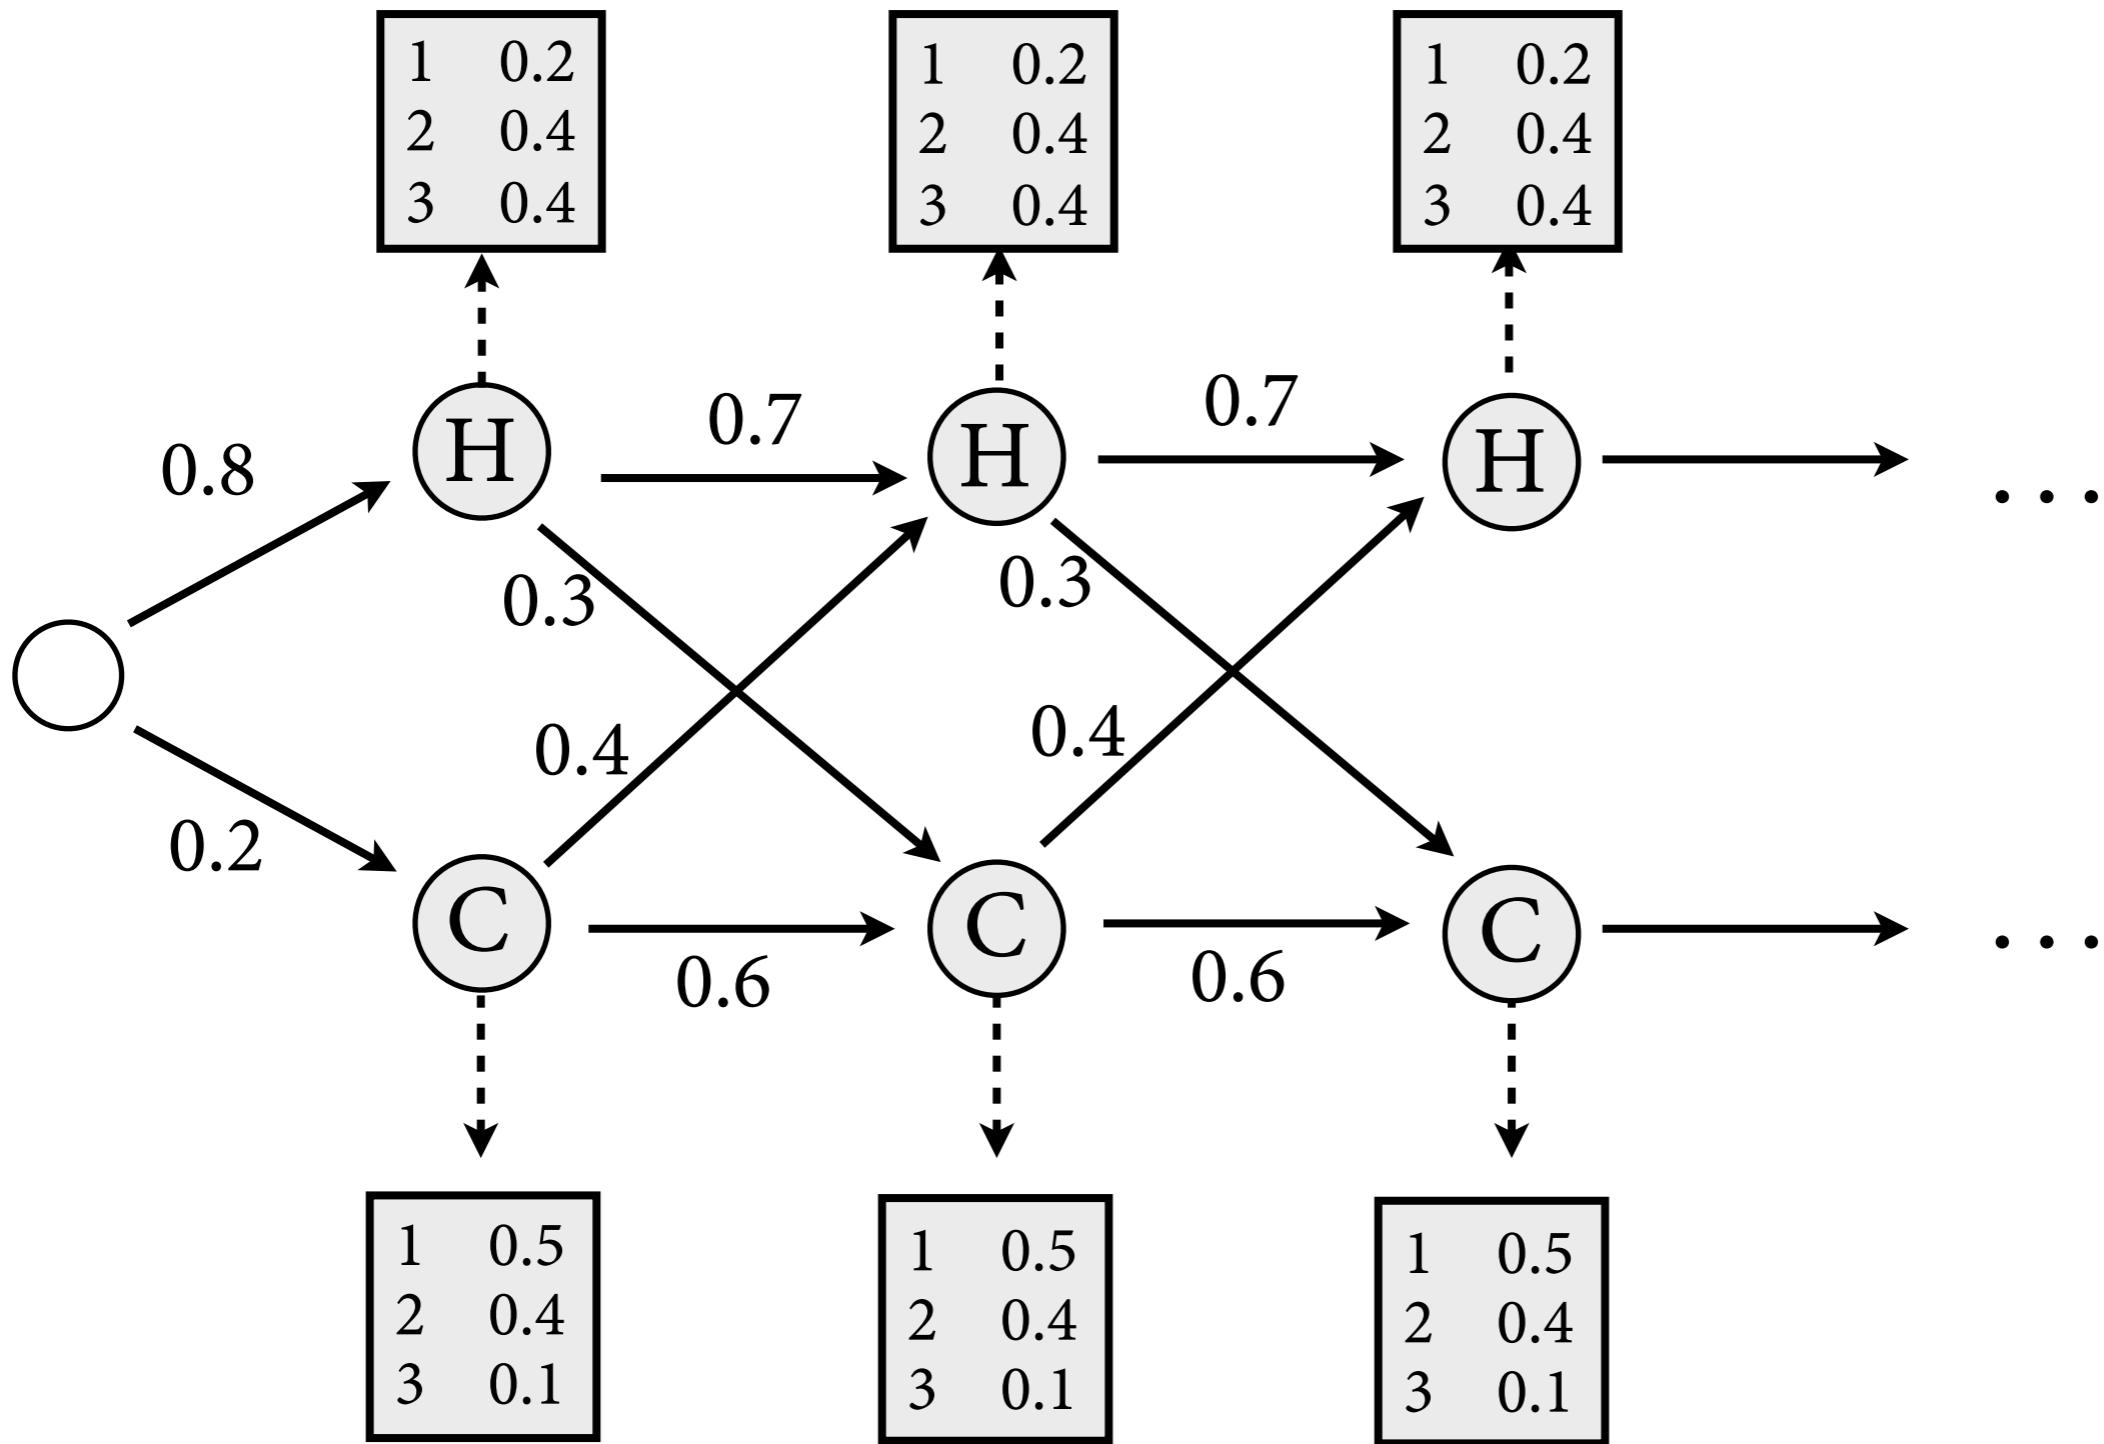

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

- Once we have calculated all V values, we can easily calculate prob of best path:

$$\max_{x_1, \dots, x_T} P(x_1, y_1, \dots, x_T, y_T) = \max_{q \in Q} V_T(q)$$

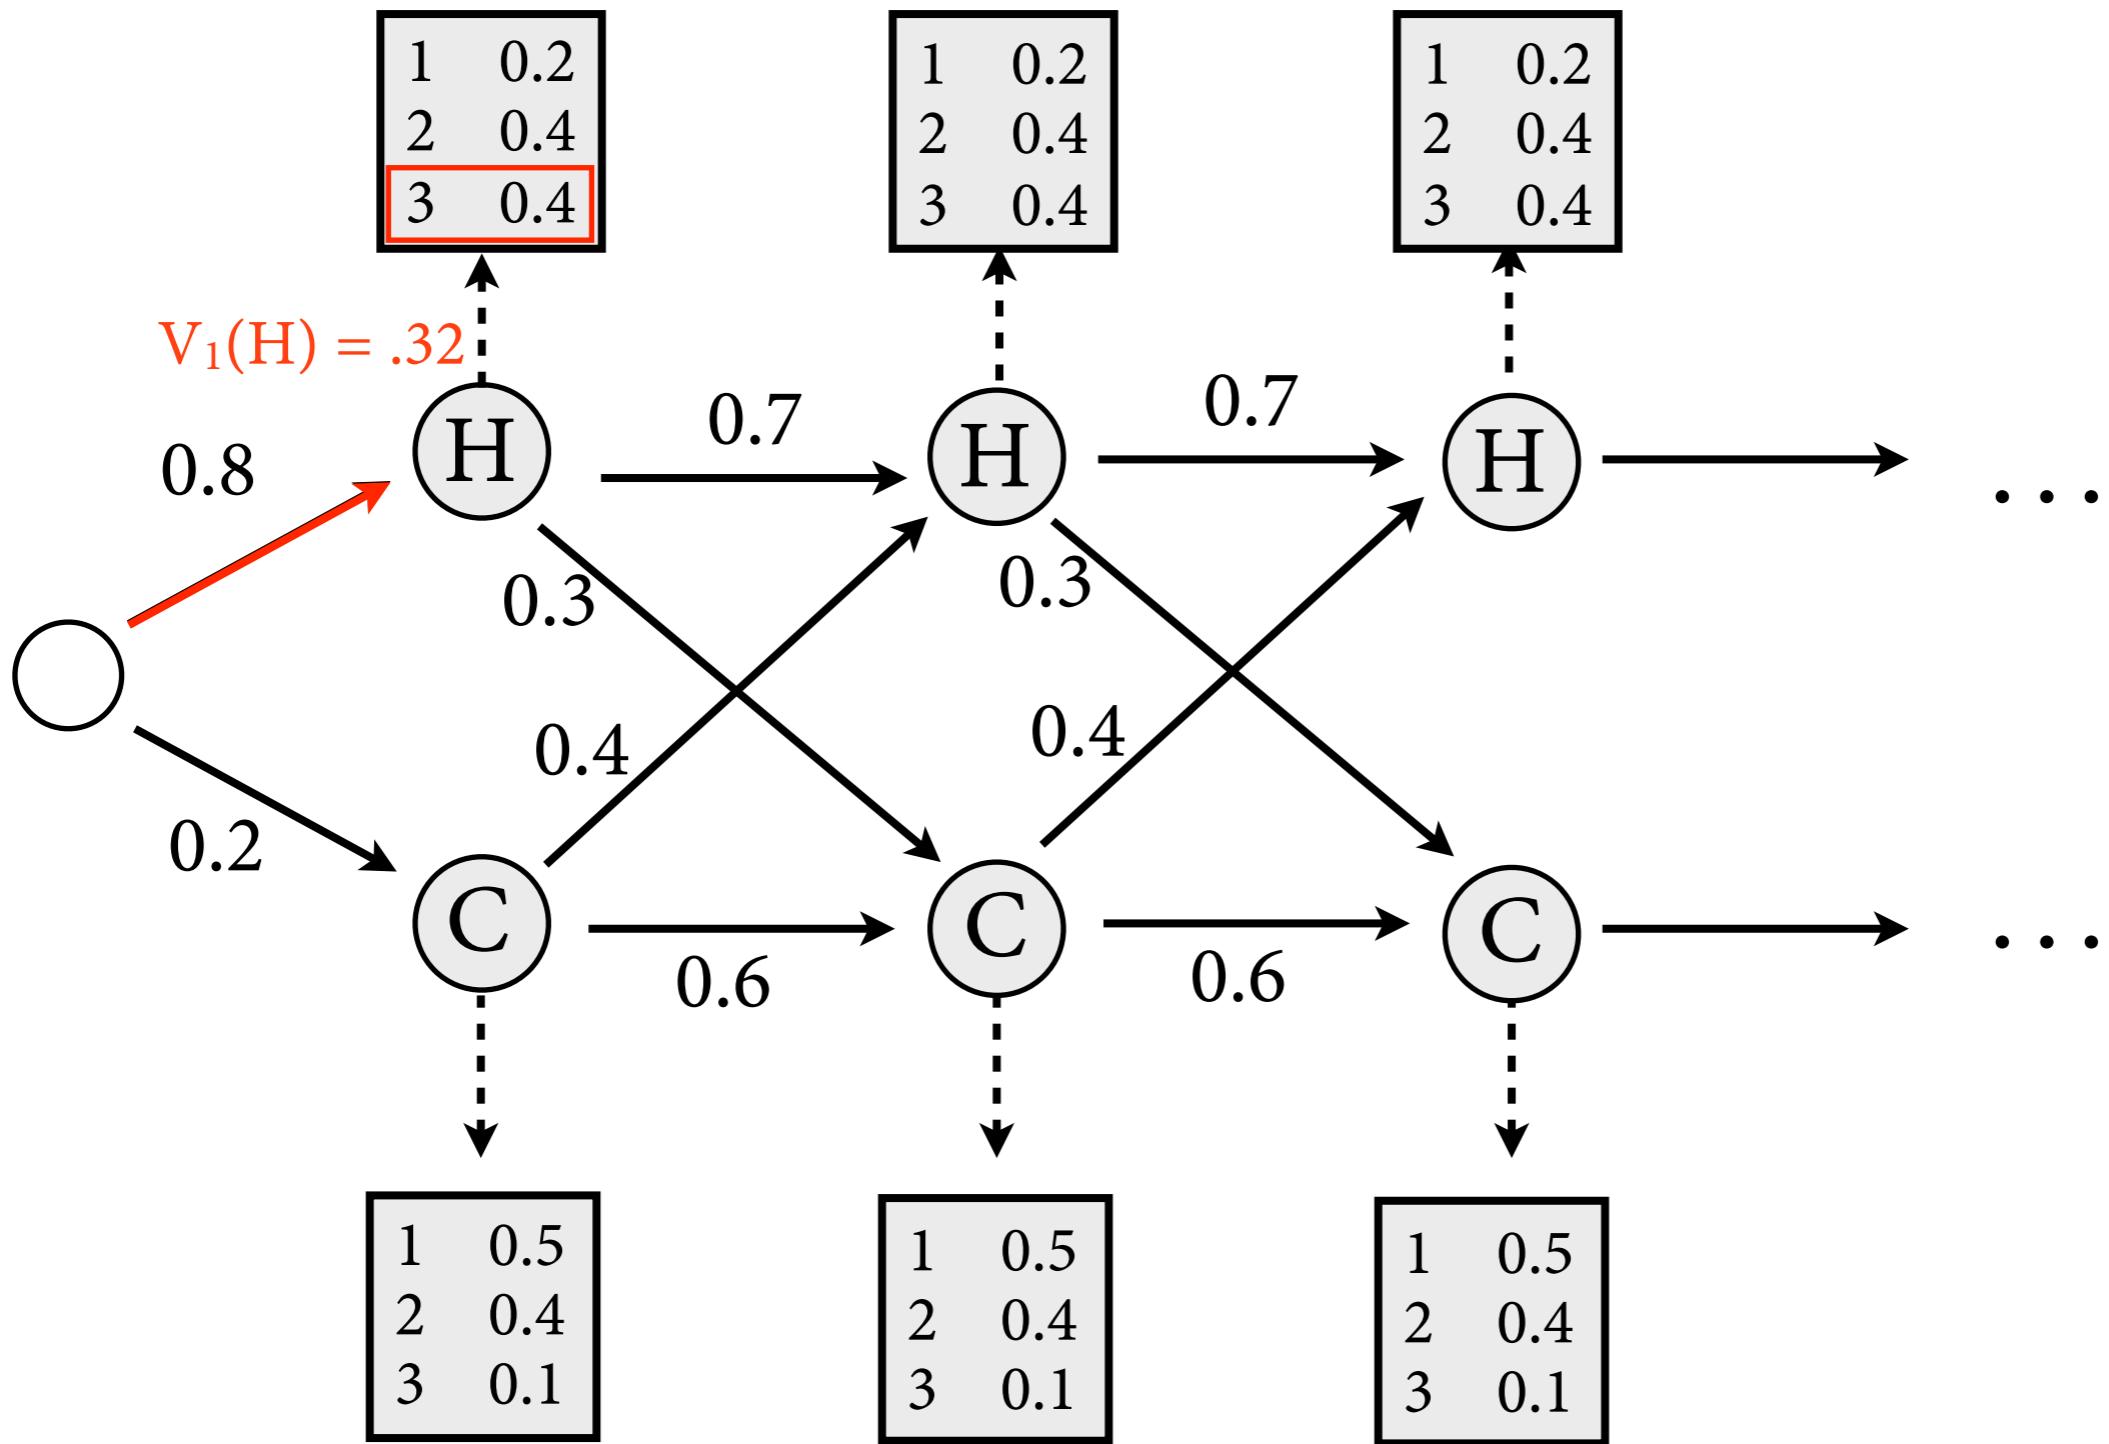

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

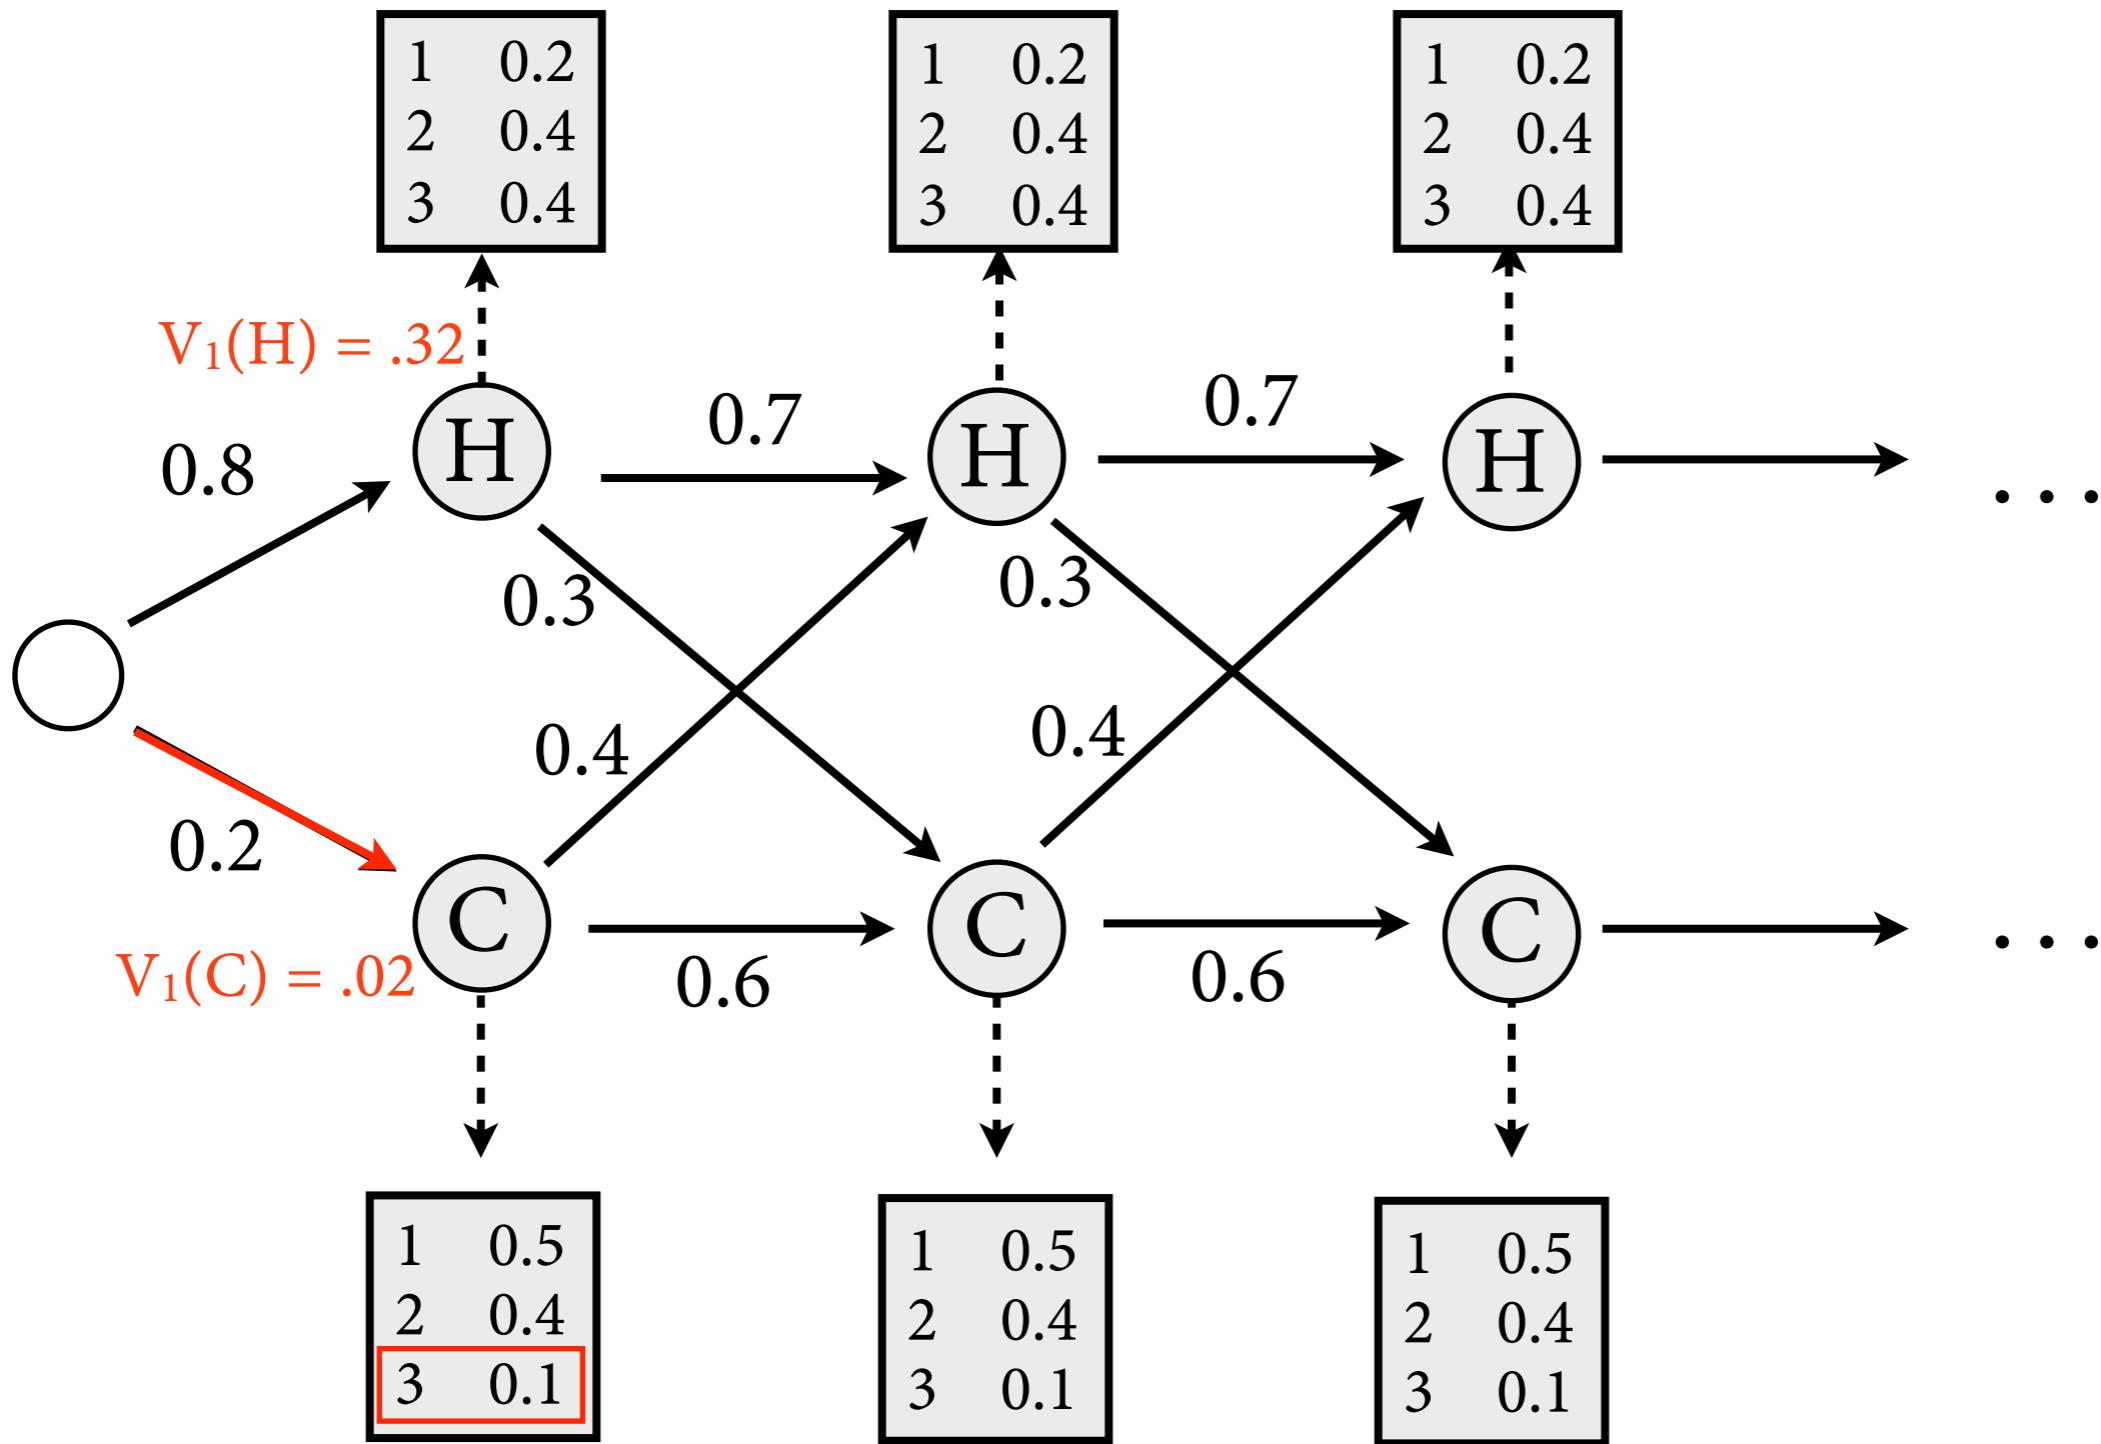

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

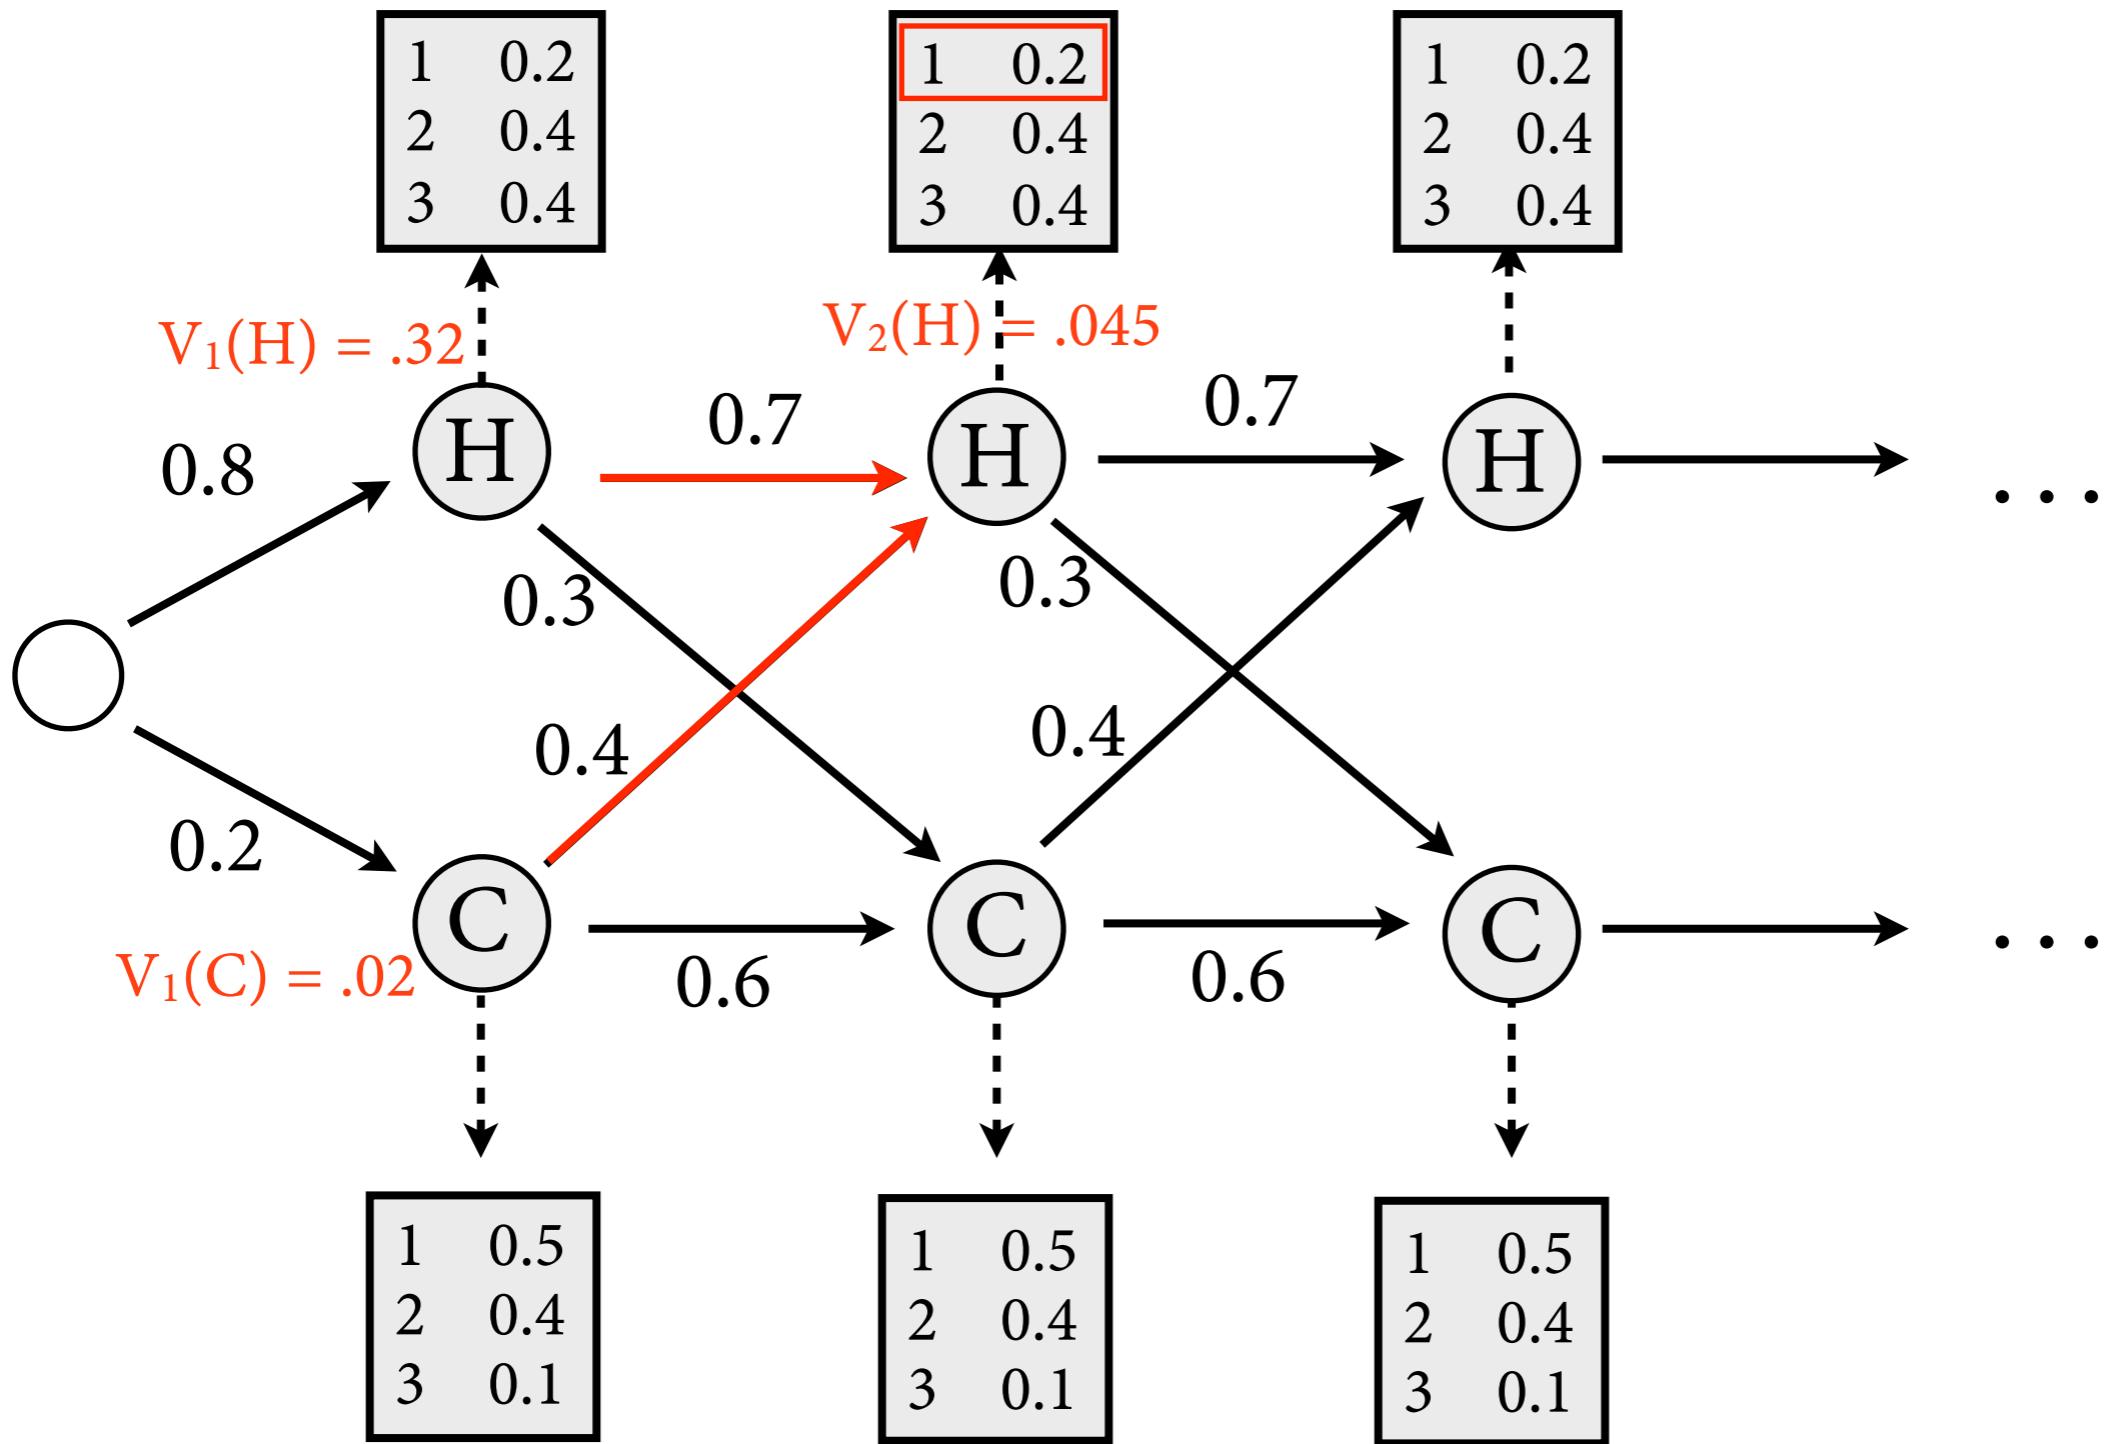

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

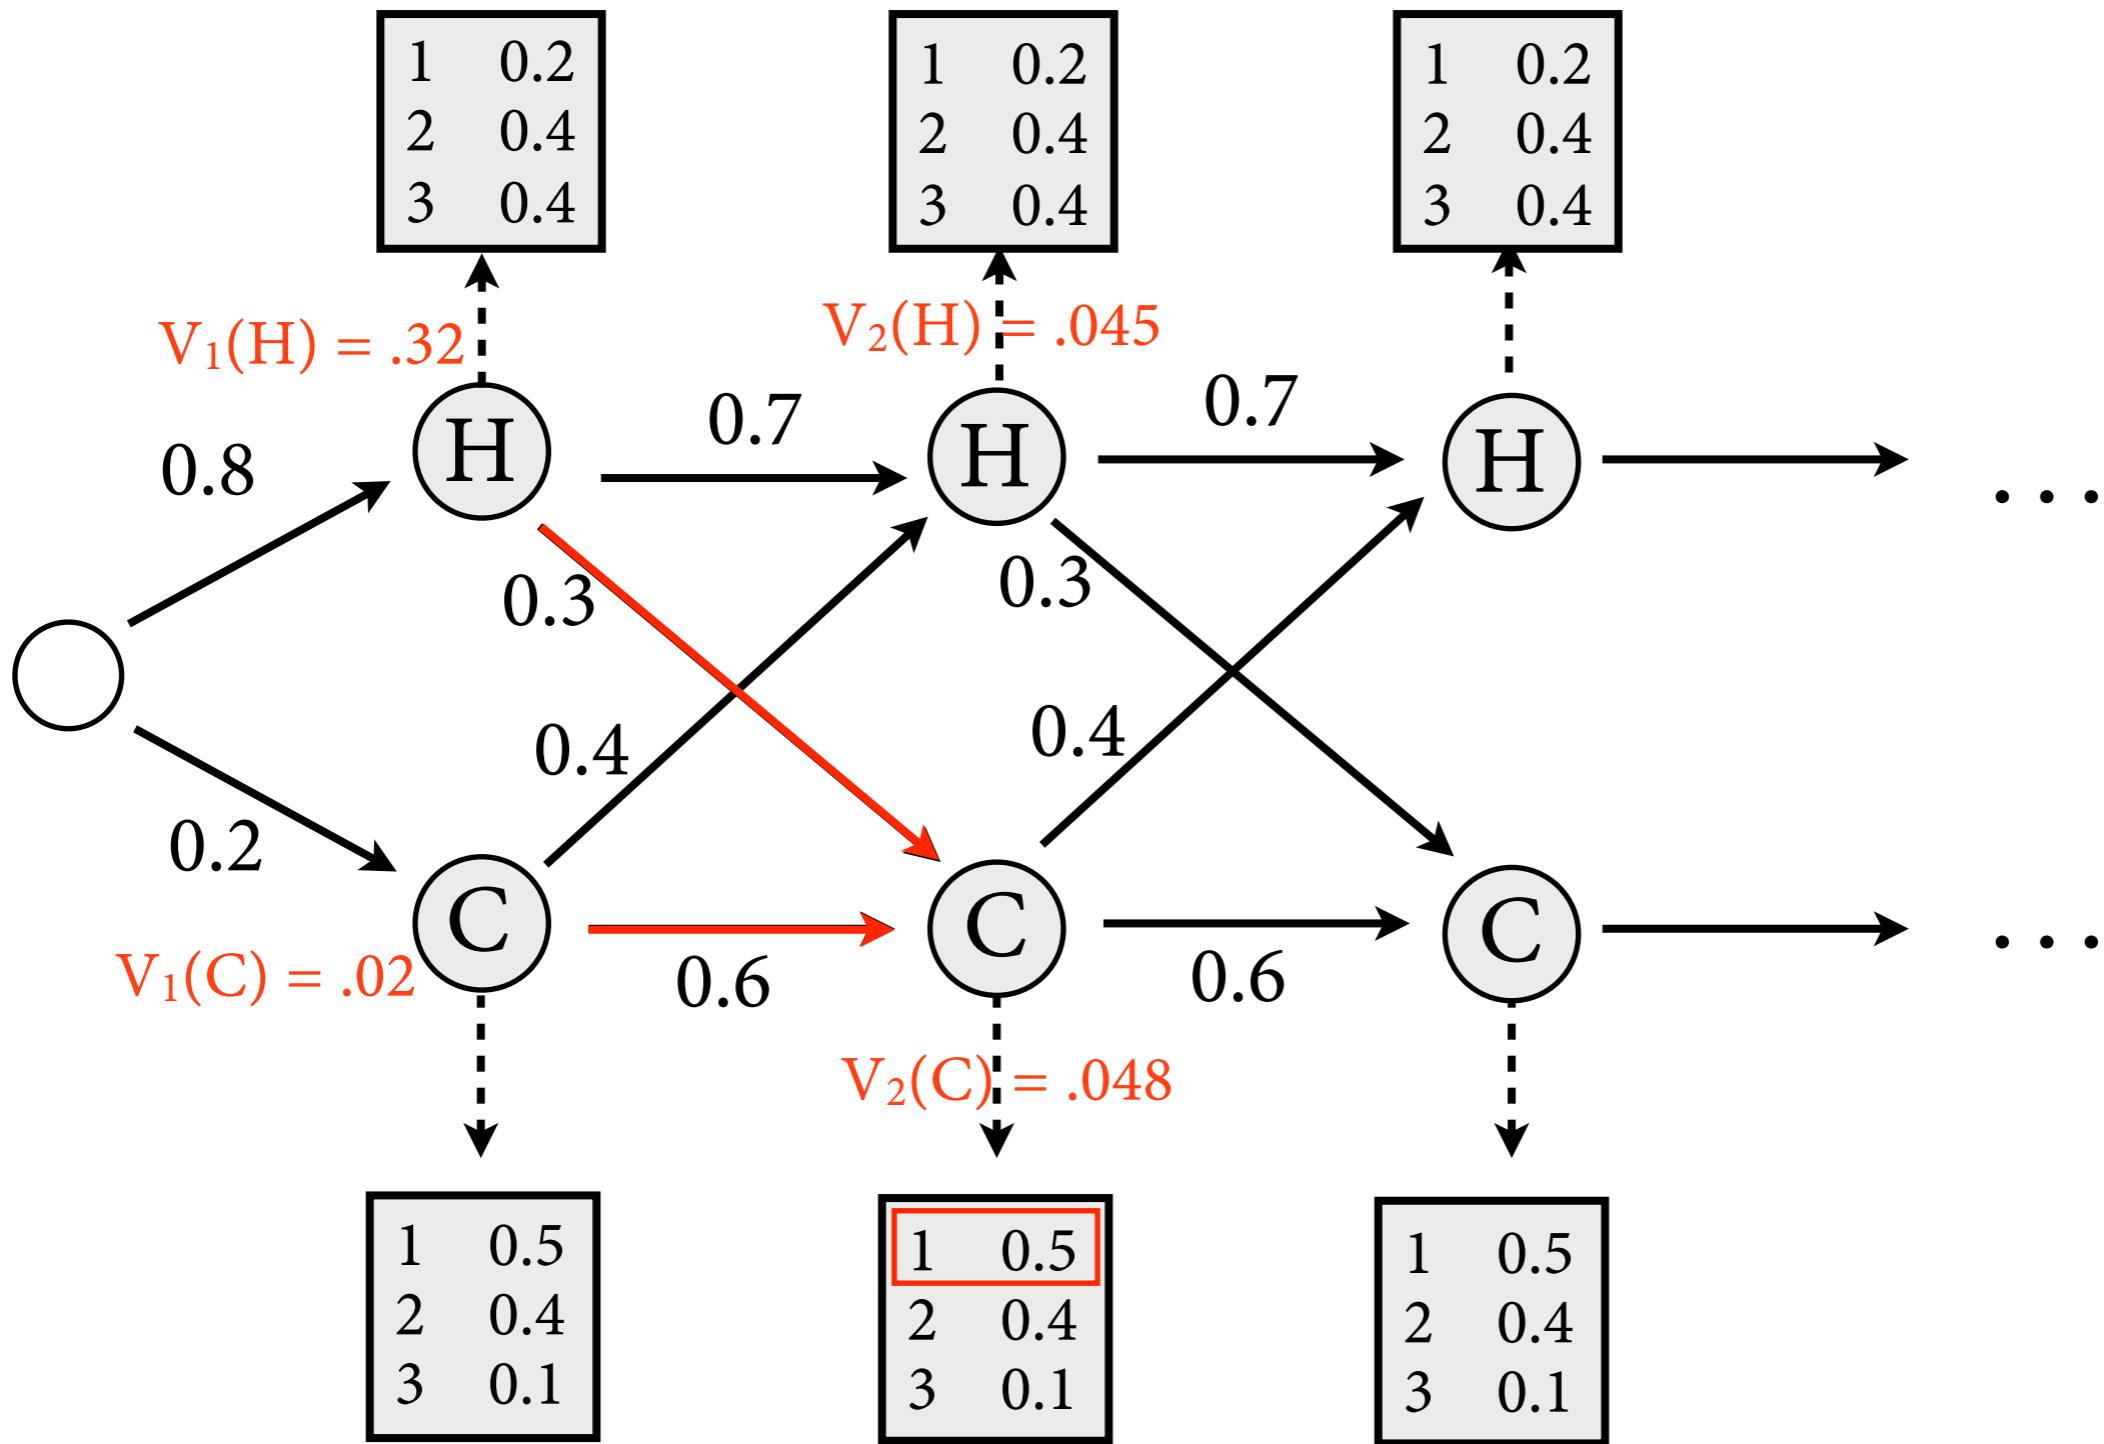

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

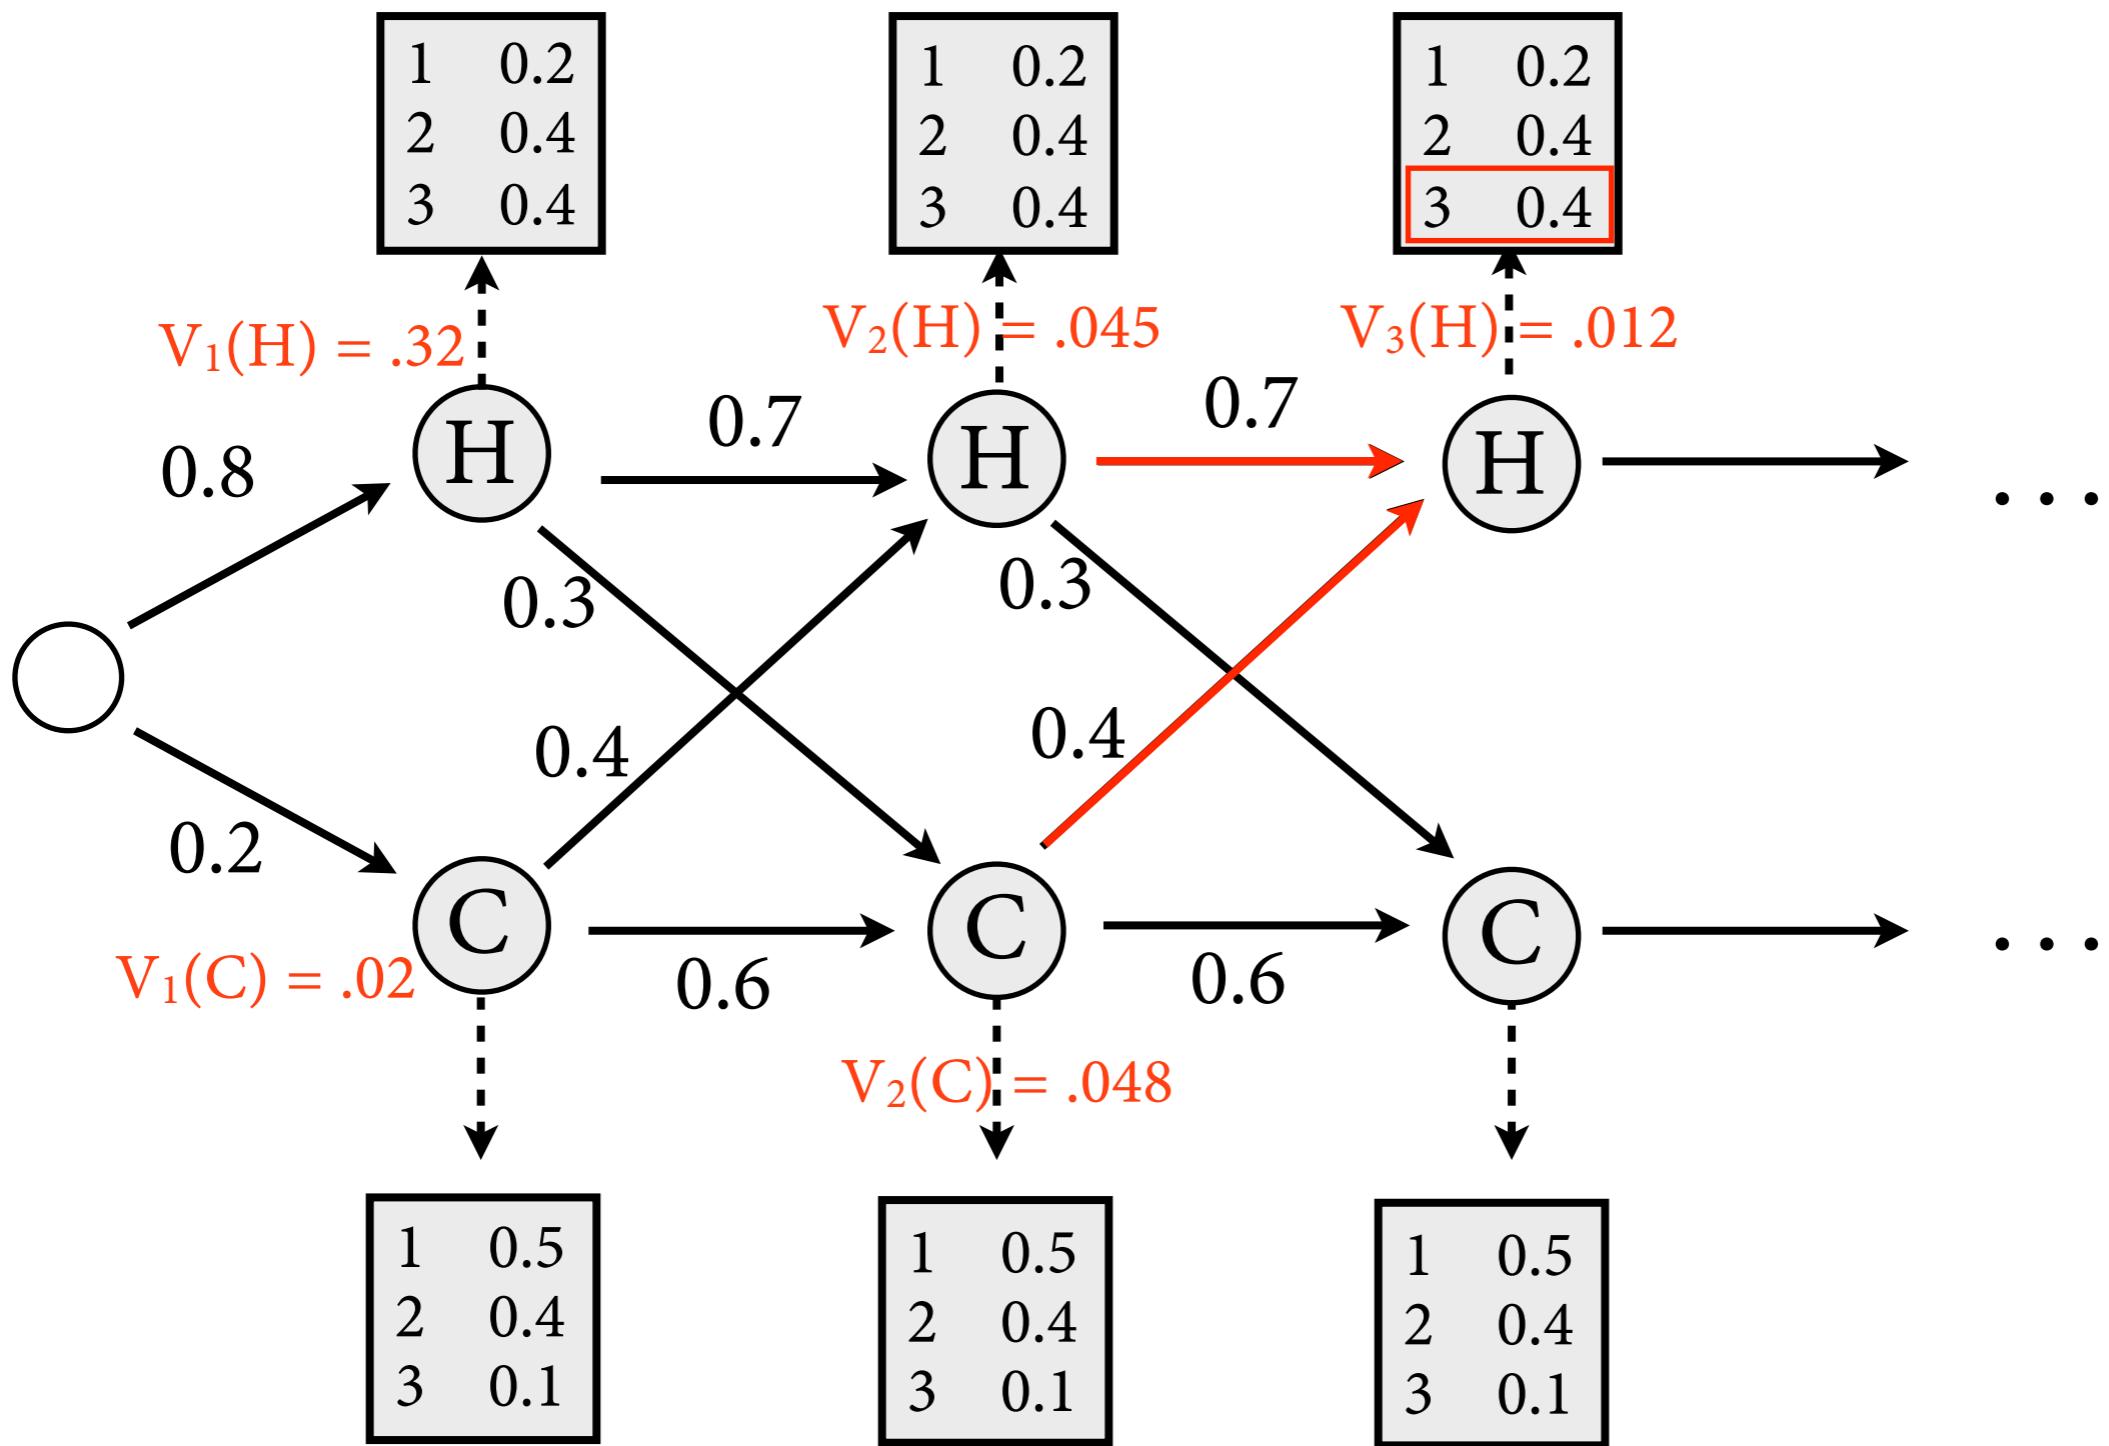

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

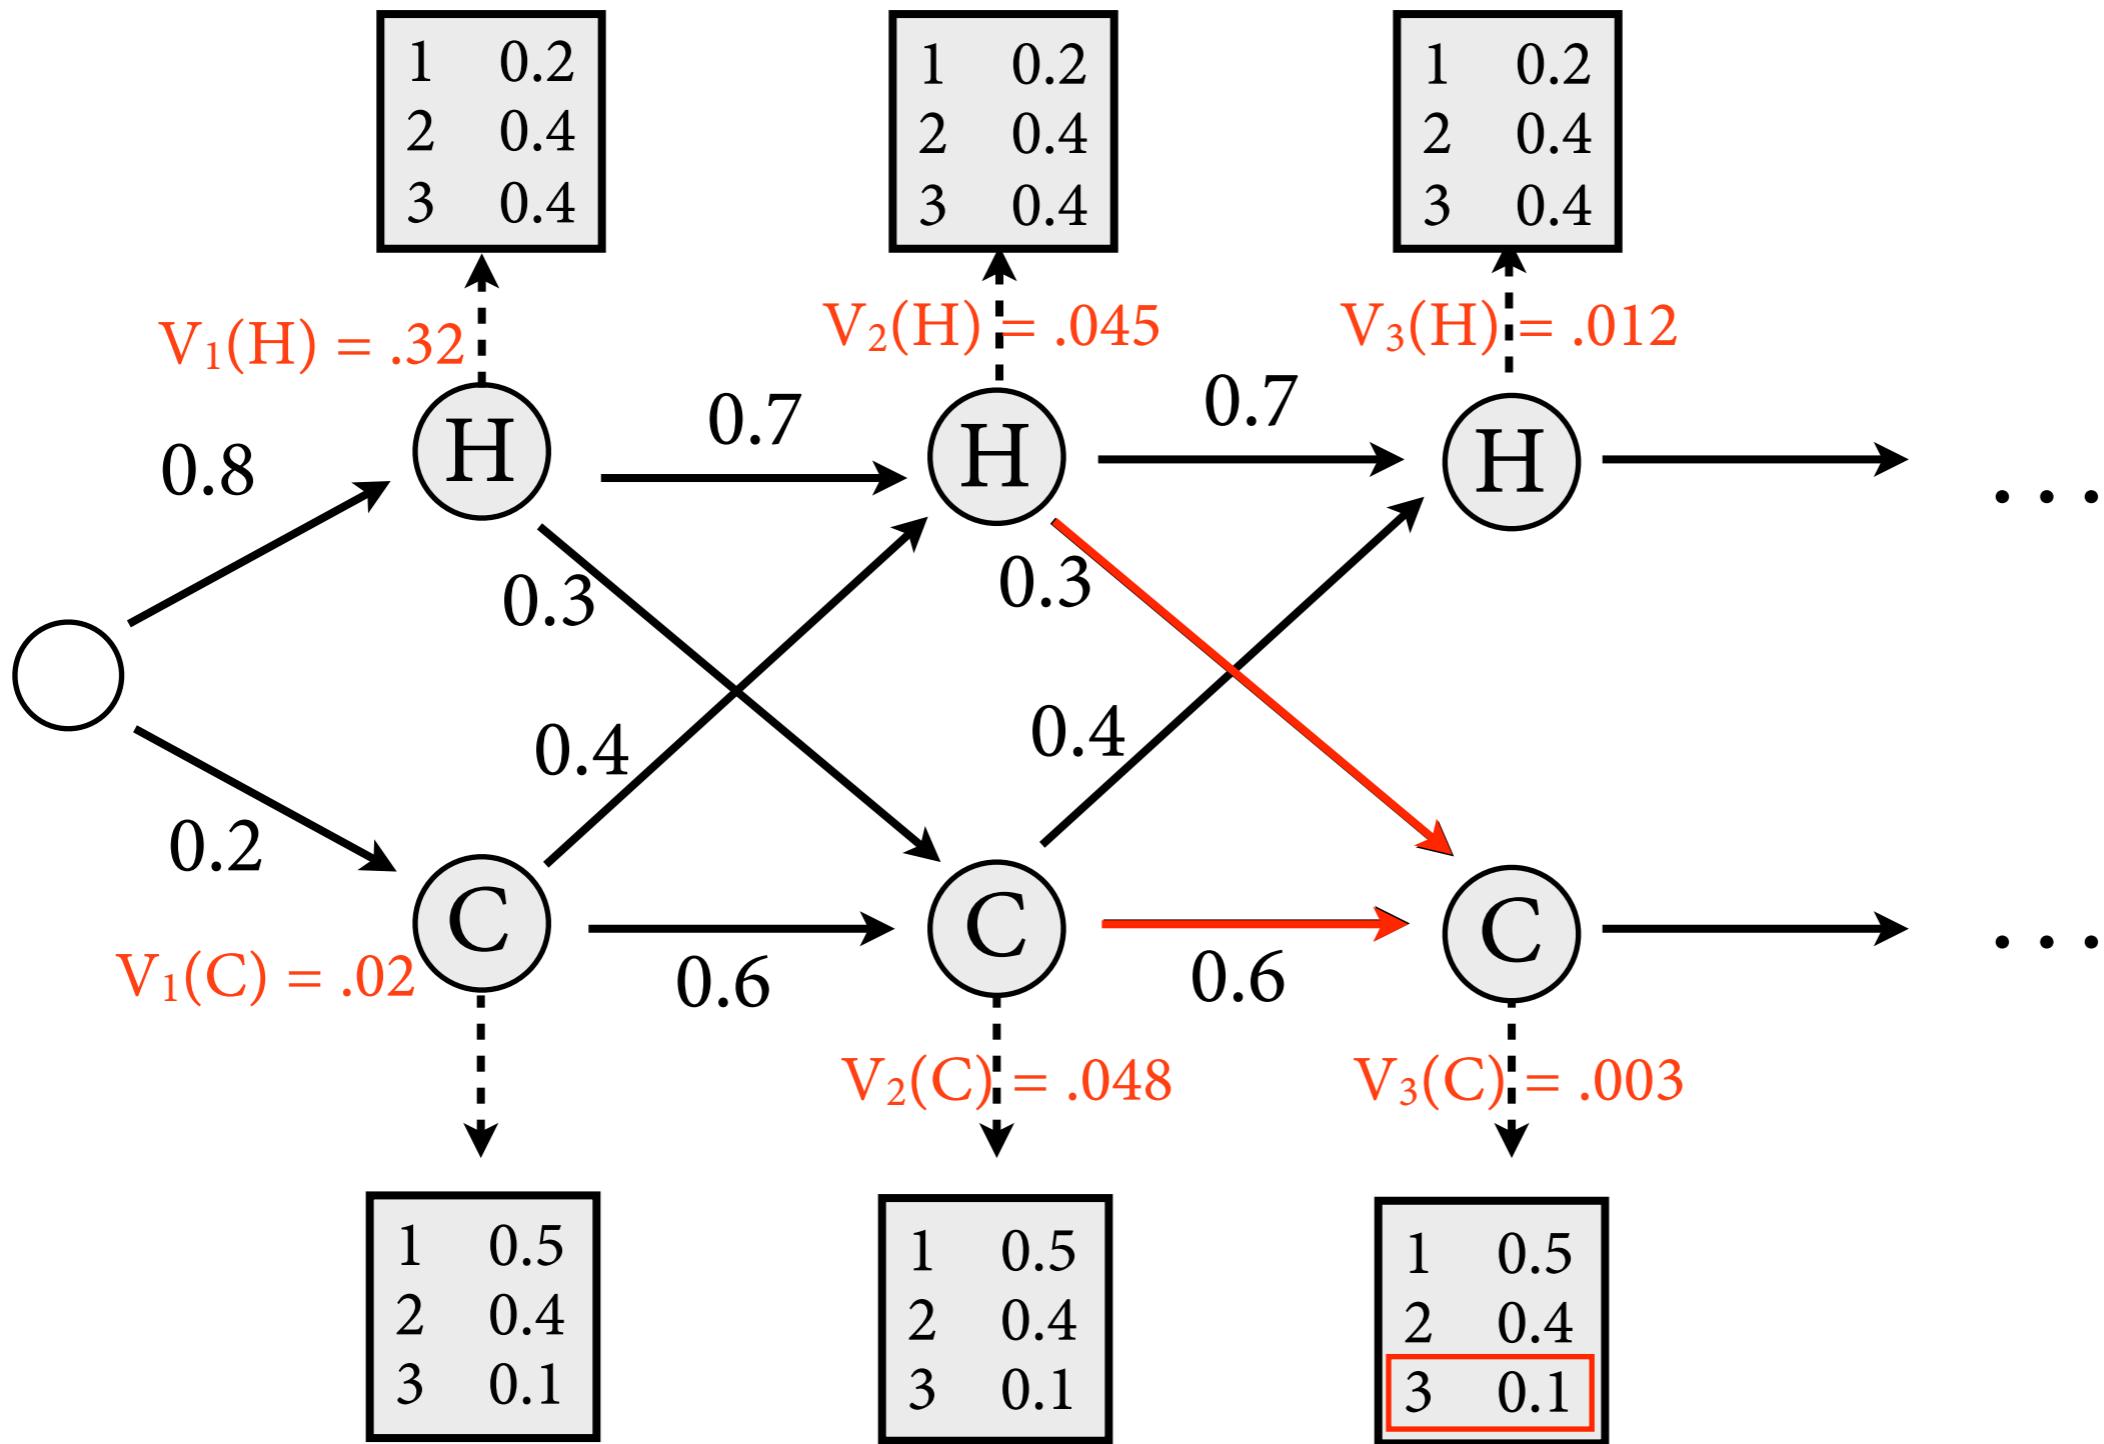

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

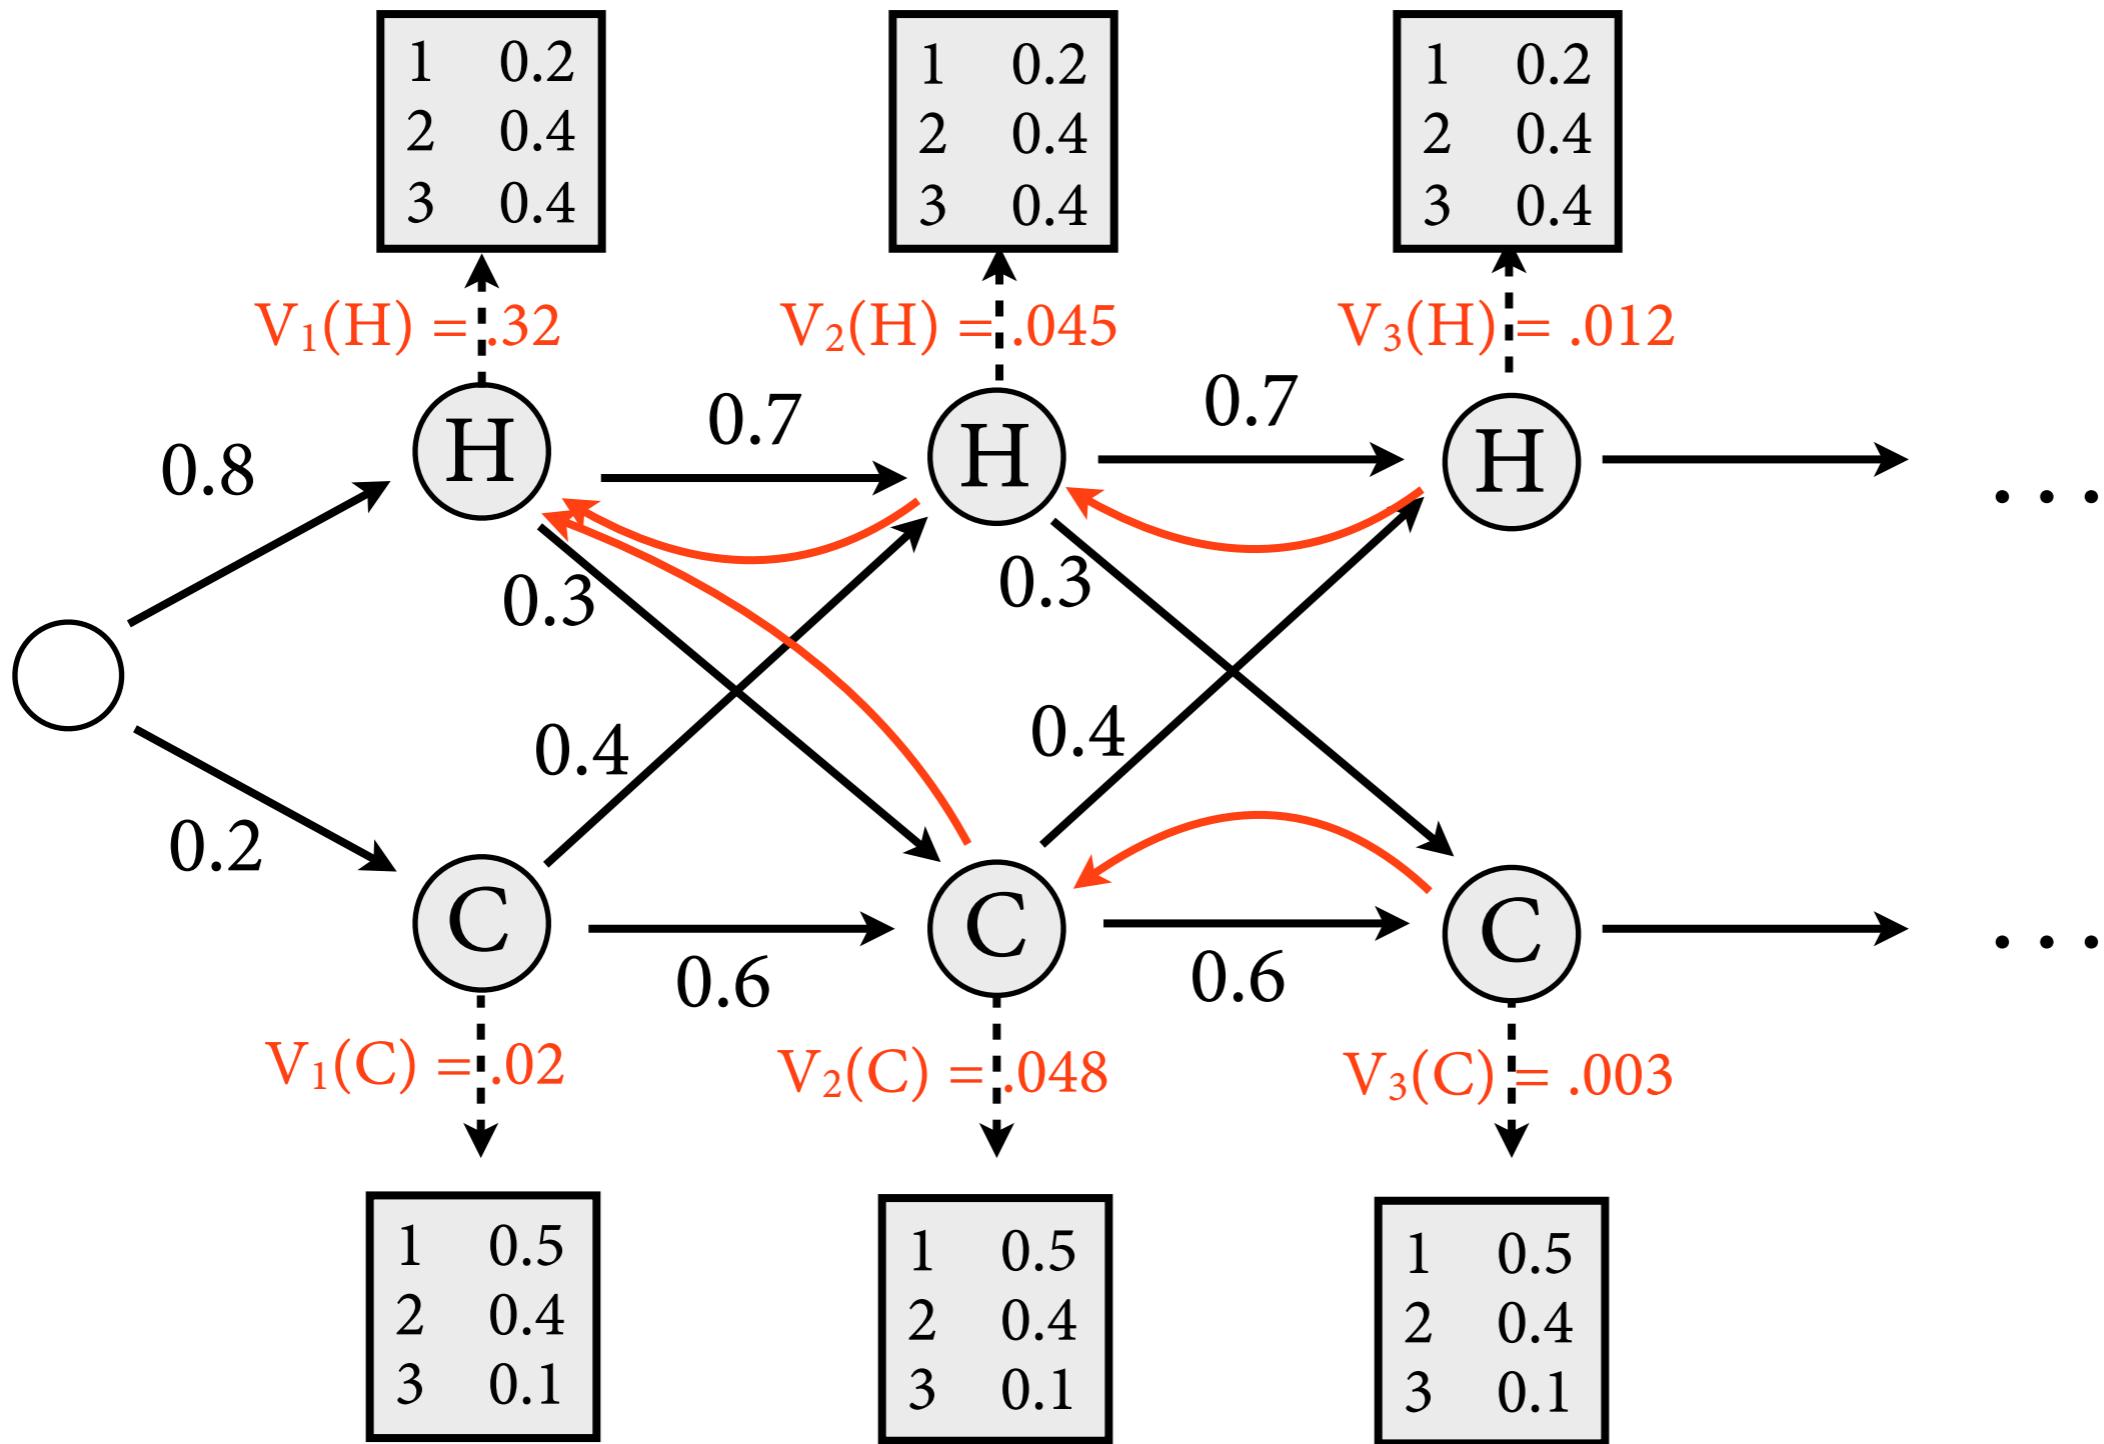

Backpointers

- In the end, we need to reconstruct the sequence of states x_1, \dots, x_T with max probability.
- For each t, j : remember the value of i for which the maximum was achieved in *backpointer* $bp_t(j)$.

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

- Then just follow backpointers from right to left.

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

Question 1: Likelihood, $P(y)$

- How likely is it that Jason Eisner ate 3 ice creams on day 1, 1 ice cream on day 2, 3 ice creams on day 3?
- Want to compute: $P(3, 1, 3)$.
- Same problem as with max:
 - Output 3, 1, 3 can be emitted by many different state sequences.
 - Obtain by marginalization:
 - Naive computation is far too slow.

Question 1: Likelihood, $P(y)$

- How likely is it that Jason Eisner ate 3 ice creams on day 1, 1 ice cream on day 2, 3 ice creams on day 3?
- Want to compute: $P(3, 1, 3)$.
- Same problem as with max:
 - Output 3, 1, 3 can be emitted by many different state sequences.
 - Obtain by marginalization:

$$P(3, 1, 3) = \sum_{x_1, x_2, x_3 \in Q} P(x_1, 3, x_2, 1, x_3, 3)$$

- Naive computation is far too slow.

The Forward Algorithm

- Key idea: *Forward probability* $\alpha_t(j)$ that HMM outputs y_1, \dots, y_t and then ends in $X_t = q_j$.

$$\begin{aligned}\alpha_t(j) &= P(y_1, \dots, y_t, X_t = q_j) \\ &= \sum_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, X_1 = x_1, \dots, X_{t-1} = x_{t-1}, X_t = q_j)\end{aligned}$$

- From this, can compute easily

$$P(y_1, \dots, y_T) = \sum_{q \in Q} \alpha_T(q)$$

The Forward Algorithm

$$\alpha_t(j) = P(y_1, \dots, y_t, X_t = q_j)$$

- Base case, $t = 1$:

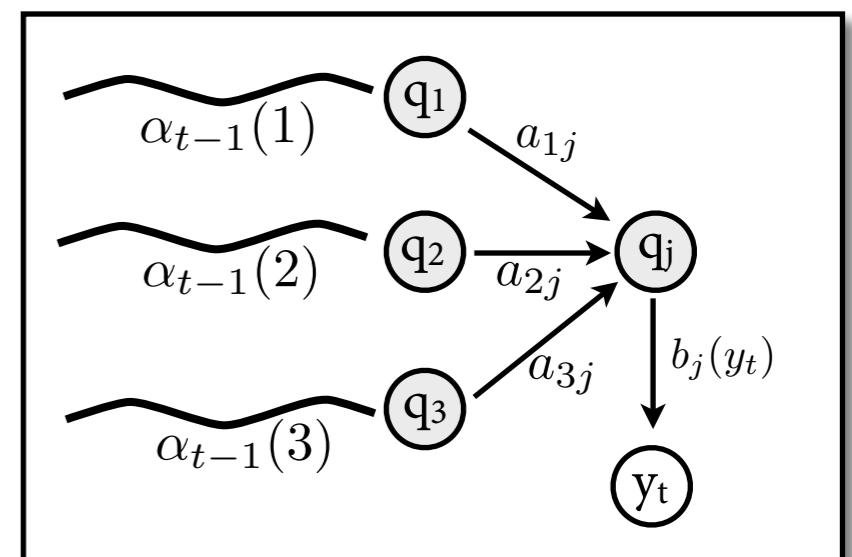

$$\alpha_1(j) = P(y_1, X_1 = q_j) = b_j(y_1) \cdot a_{0j}$$

- Inductive case, compute for $t = 2, \dots, T$:

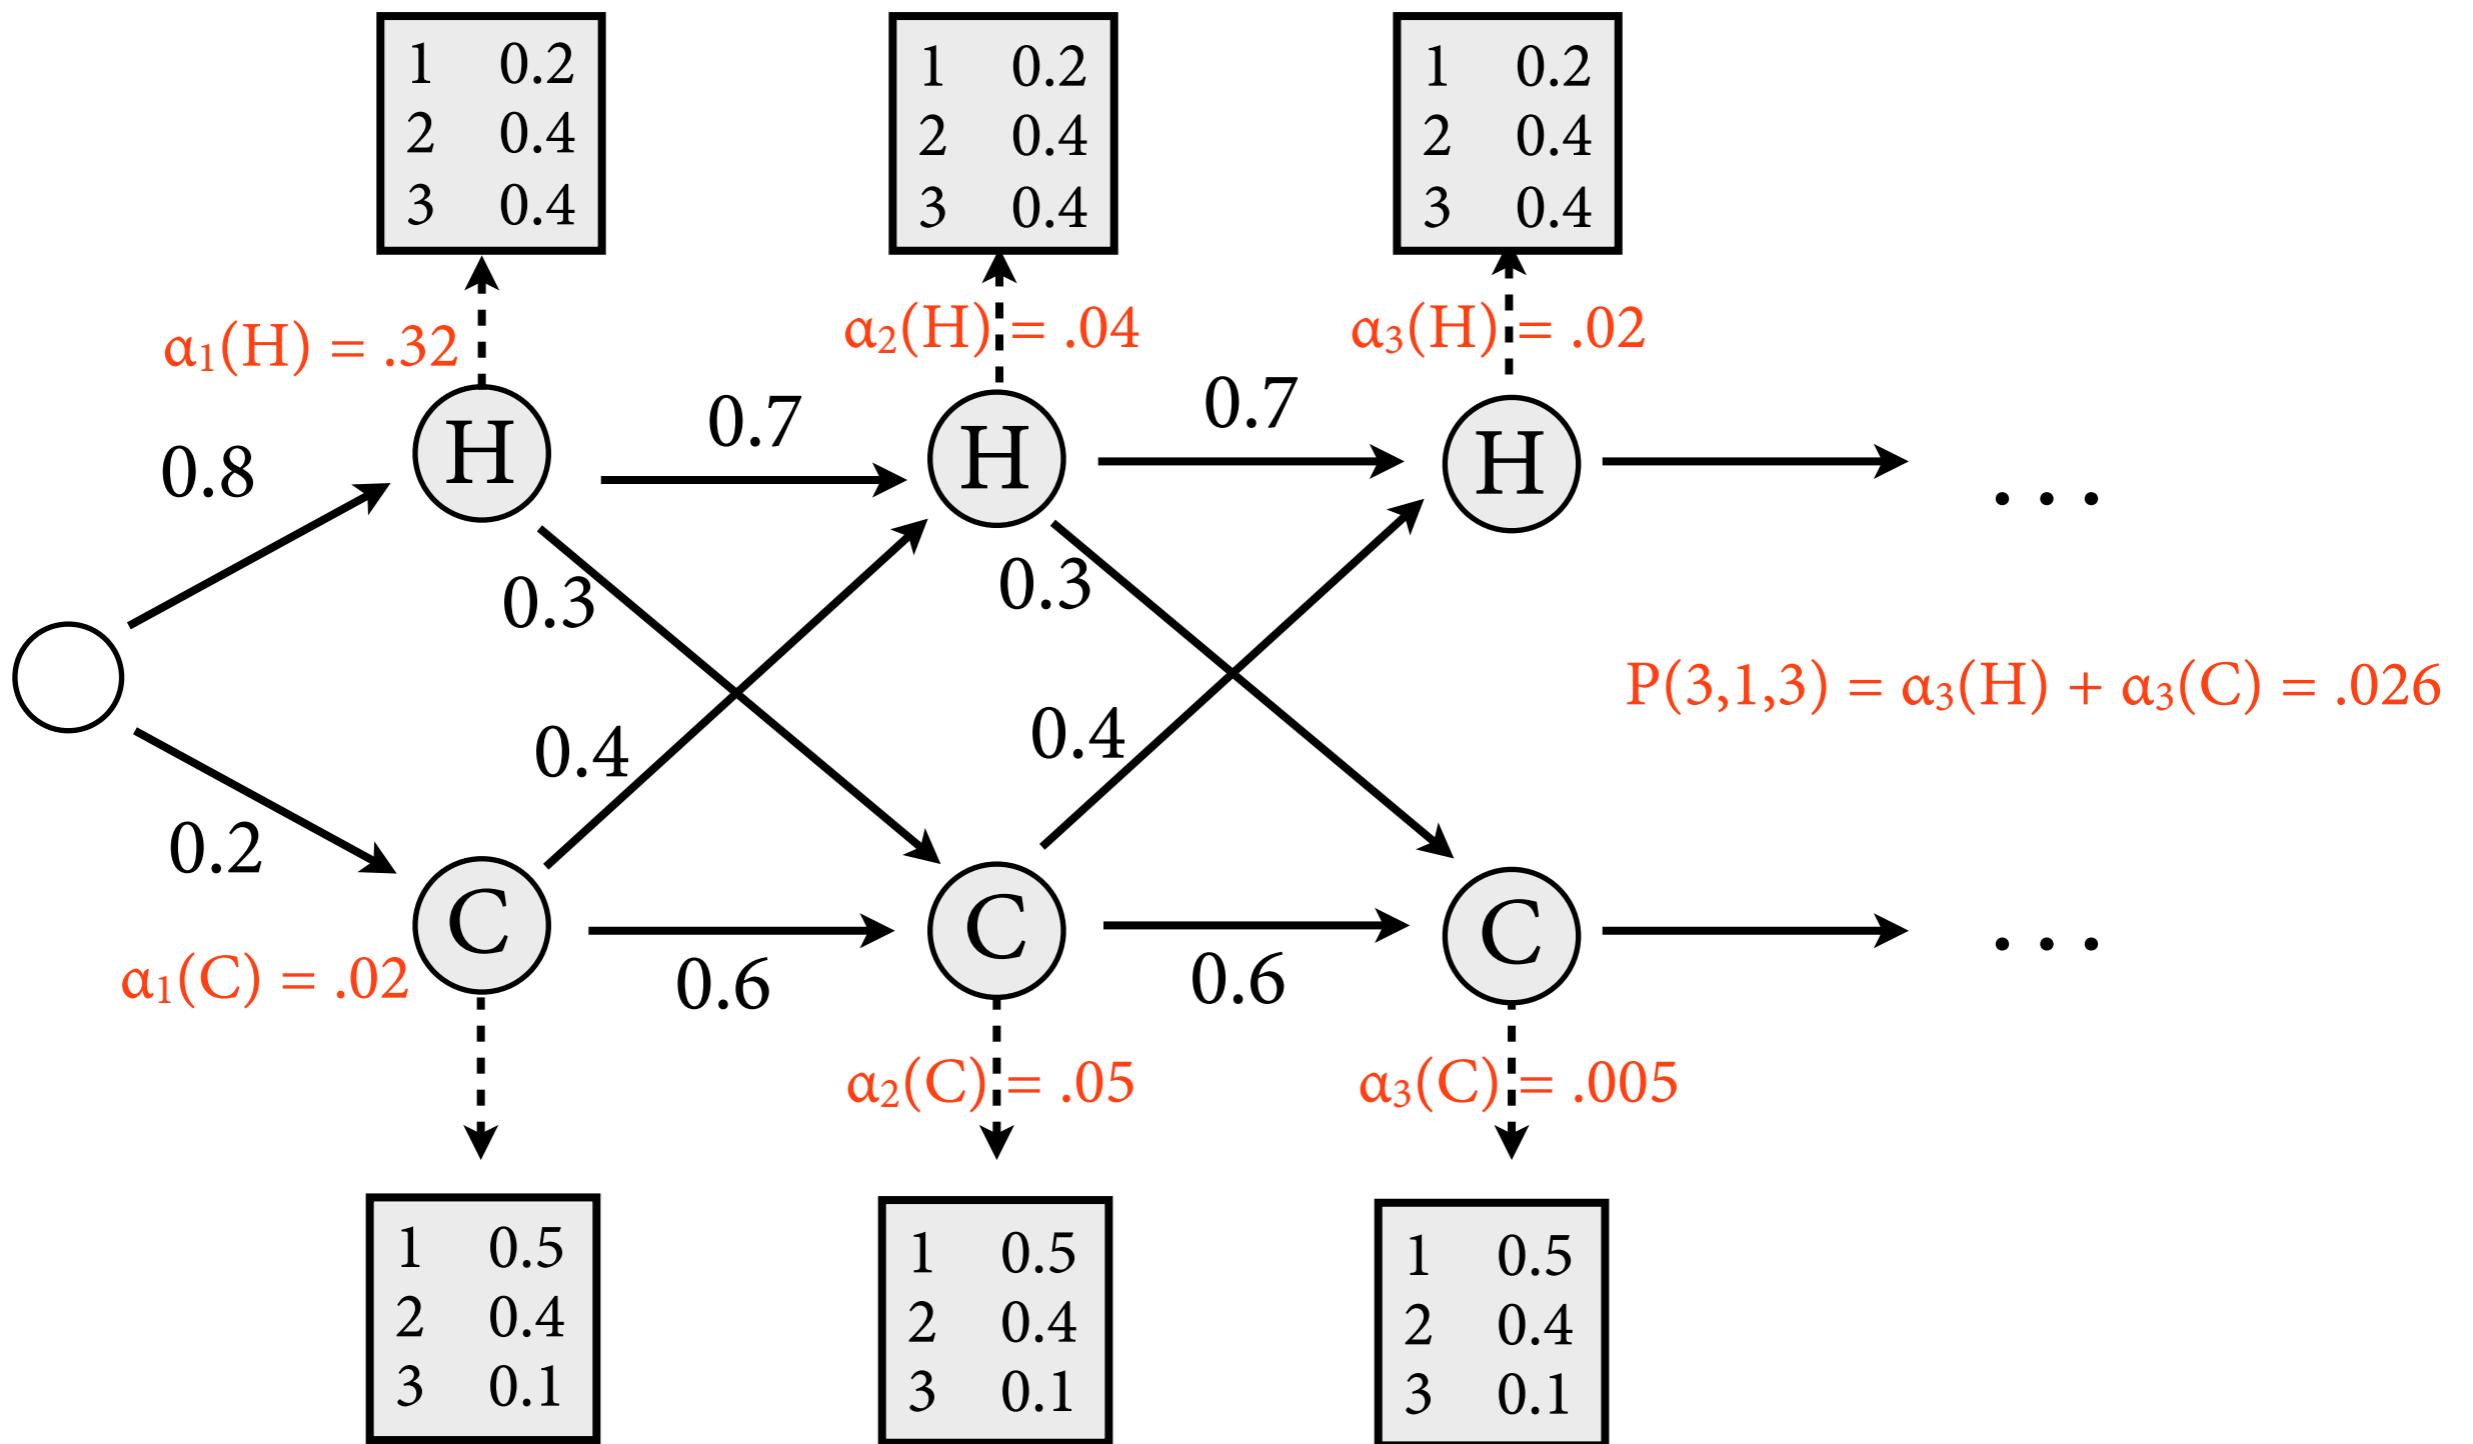

$$\alpha_t(j) = P(y_1, \dots, y_t, X_t = q_j)$$

$$= \sum_{i=1}^N P(y_1, \dots, y_{t-1}, X_{t-1} = q_i) \cdot P(X_t = q_j \mid X_{t-1} = q_i) \cdot P(y_t \mid X_t = q_j)$$

$$= \sum_{i=1}^N \alpha_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

P(3,1,3) with Forward

Runtime

- Forward and Viterbi have the same runtime, dominated by inductive step:

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

- Compute $N \cdot T$ values for $V_t(j)$. Each computation step requires iteration over N predecessor states.
- Total runtime is $O(N^2 \cdot T)$, i.e.
 - ▶ linear in sentence length
 - ▶ quadratic in size of tag set

Summary

- Hidden Markov Models popular model for POS tagging (and other applications, see later).
- Two coupled random processes:
 - ▶ bigram model for hidden states
 - ▶ model for producing observable output from state
- Efficient algorithms for common problems:
 - ▶ Likelihood computation: Forward algorithm
 - ▶ Best state sequence: Viterbi algorithm.
