Let's play a game

- I will write a sequence of part-of-speech tags and of words on the board.
- You take turns in giving me POS tags and words, and I will write them down.

Penn Treebank POS tags

Tag	Description	Example	Tag	Description	Example
CC	Coordin. Conjunction	<i>and, but, or</i>	SYM	Symbol	<i>+, %, &</i>
CD	Cardinal number	<i>one, two, three</i>	TO	“to”	<i>to</i>
DT	Determiner	<i>a, the</i>	UH	Interjection	<i>ah, oops</i>
EX	Existential ‘there’	<i>there</i>	VB	Verb, base form	<i>eat</i>
FW	Foreign word	<i>mea culpa</i>	VBD	Verb, past tense	<i>ate</i>
IN	Preposition/sub-conj	<i>of, in, by</i>	VBG	Verb, gerund	<i>eating</i>
JJ	Adjective	<i>yellow</i>	VBN	Verb, past participle	<i>eaten</i>
JJR	Adj., comparative	<i>bigger</i>	VBP	Verb, non-3sg pres	<i>eat</i>
JJS	Adj., superlative	<i>wildest</i>	VBZ	Verb, 3sg pres	<i>eats</i>
LS	List item marker	<i>1, 2, One</i>	WDT	Wh-determiner	<i>which, that</i>
MD	Modal	<i>can, should</i>	WP	Wh-pronoun	<i>what, who</i>
NN	Noun, sing. or mass	<i>llama</i>	WP\$	Possessive wh-	<i>whose</i>
NNS	Noun, plural	<i>llamas</i>	WRB	Wh-adverb	<i>how, where</i>
NNP	Proper noun, singular	<i>IBM</i>	\$	Dollar sign	<i>\$</i>
NNPS	Proper noun, plural	<i>Carolinas</i>	#	Pound sign	<i>#</i>
PDT	Predeterminer	<i>all, both</i>	“	Left quote	<i>(‘ or “)</i>
POS	Possessive ending	<i>’s</i>	”	Right quote	<i>(’ or ”)</i>
PP	Personal pronoun	<i>I, you, he</i>	(Left parenthesis	<i>([, ({ , <)</i>
PP\$	Possessive pronoun	<i>your, one’s</i>)	Right parenthesis	<i>([,) , } , >)</i>
RB	Adverb	<i>quickly, never</i>	,	Comma	<i>,</i>
RBR	Adverb, comparative	<i>faster</i>	.	Sentence-final punc	<i>(. ! ?)</i>
RBS	Adverb, superlative	<i>fastest</i>	:	Mid-sentence punc	<i>(: ; ... – -)</i>
RP	Particle	<i>up, off</i>			

Hidden Markov Models

- Last week's generative story: generate words at random from n-gram model $P(w_n \mid w_1, \dots, w_{n-1})$.
- Replace with new generative story:
 - ▶ Language is generated by a two-step process.
 - ▶ First, generate sequence of hidden POS tags t_1, \dots, t_T tag by tag, left to right from bigram model $P(t_i \mid t_{i-1})$.
 - ▶ Independently, generate an observable word w_i from each t_i , at random from model $P(w_i \mid t_i)$.

Question 1: Language modeling

- Given an HMM and a string w_1, \dots, w_T , what is the likelihood $P(w_1 \dots w_T)$?
- We can compute $P(w_1 \dots w_T)$ efficiently with the *forward algorithm*.

DT	NN	VBD	NNS	IN	DT	NN

$$P(\text{sentence}) = p_1 + p_2$$

Question 2: Tagging (aka Decoding)

- Given an HMM and an observed string w_1, \dots, w_T , what is the most likely sequence of hidden tags t_1, \dots, t_T ?
- We can compute $\arg \max_{t_1, \dots, t_T} P(t_1, \dots, t_T \mid w_1, \dots, w_T)$ efficiently with the *Viterbi algorithm*.

Question 3a: Supervised learning

- Given a set of POS tags and *annotated* training data $(w_1, t_1), \dots, (w_T, t_T)$, compute parameters for HMM that maximize likelihood of training data.
- Can do it with maximum likelihood estimation plus smoothing.

Secretariat	is	expected	to	race	tomorrow.	

→ next time

Question 3b: Unsupervised learning

- Given a set of POS tags and *unannotated* training data w_1, \dots, w_T , compute parameters for HMM that maximize likelihood of training data.
- Do it efficiently with the *forward-backward algorithm* (an instance of *Expectation Maximization*).

The representative put chairs on the table.

Secretariat is expected to race tomorrow.

Hidden Markov Models

- A *Hidden Markov Model* is 5-tuple consisting of

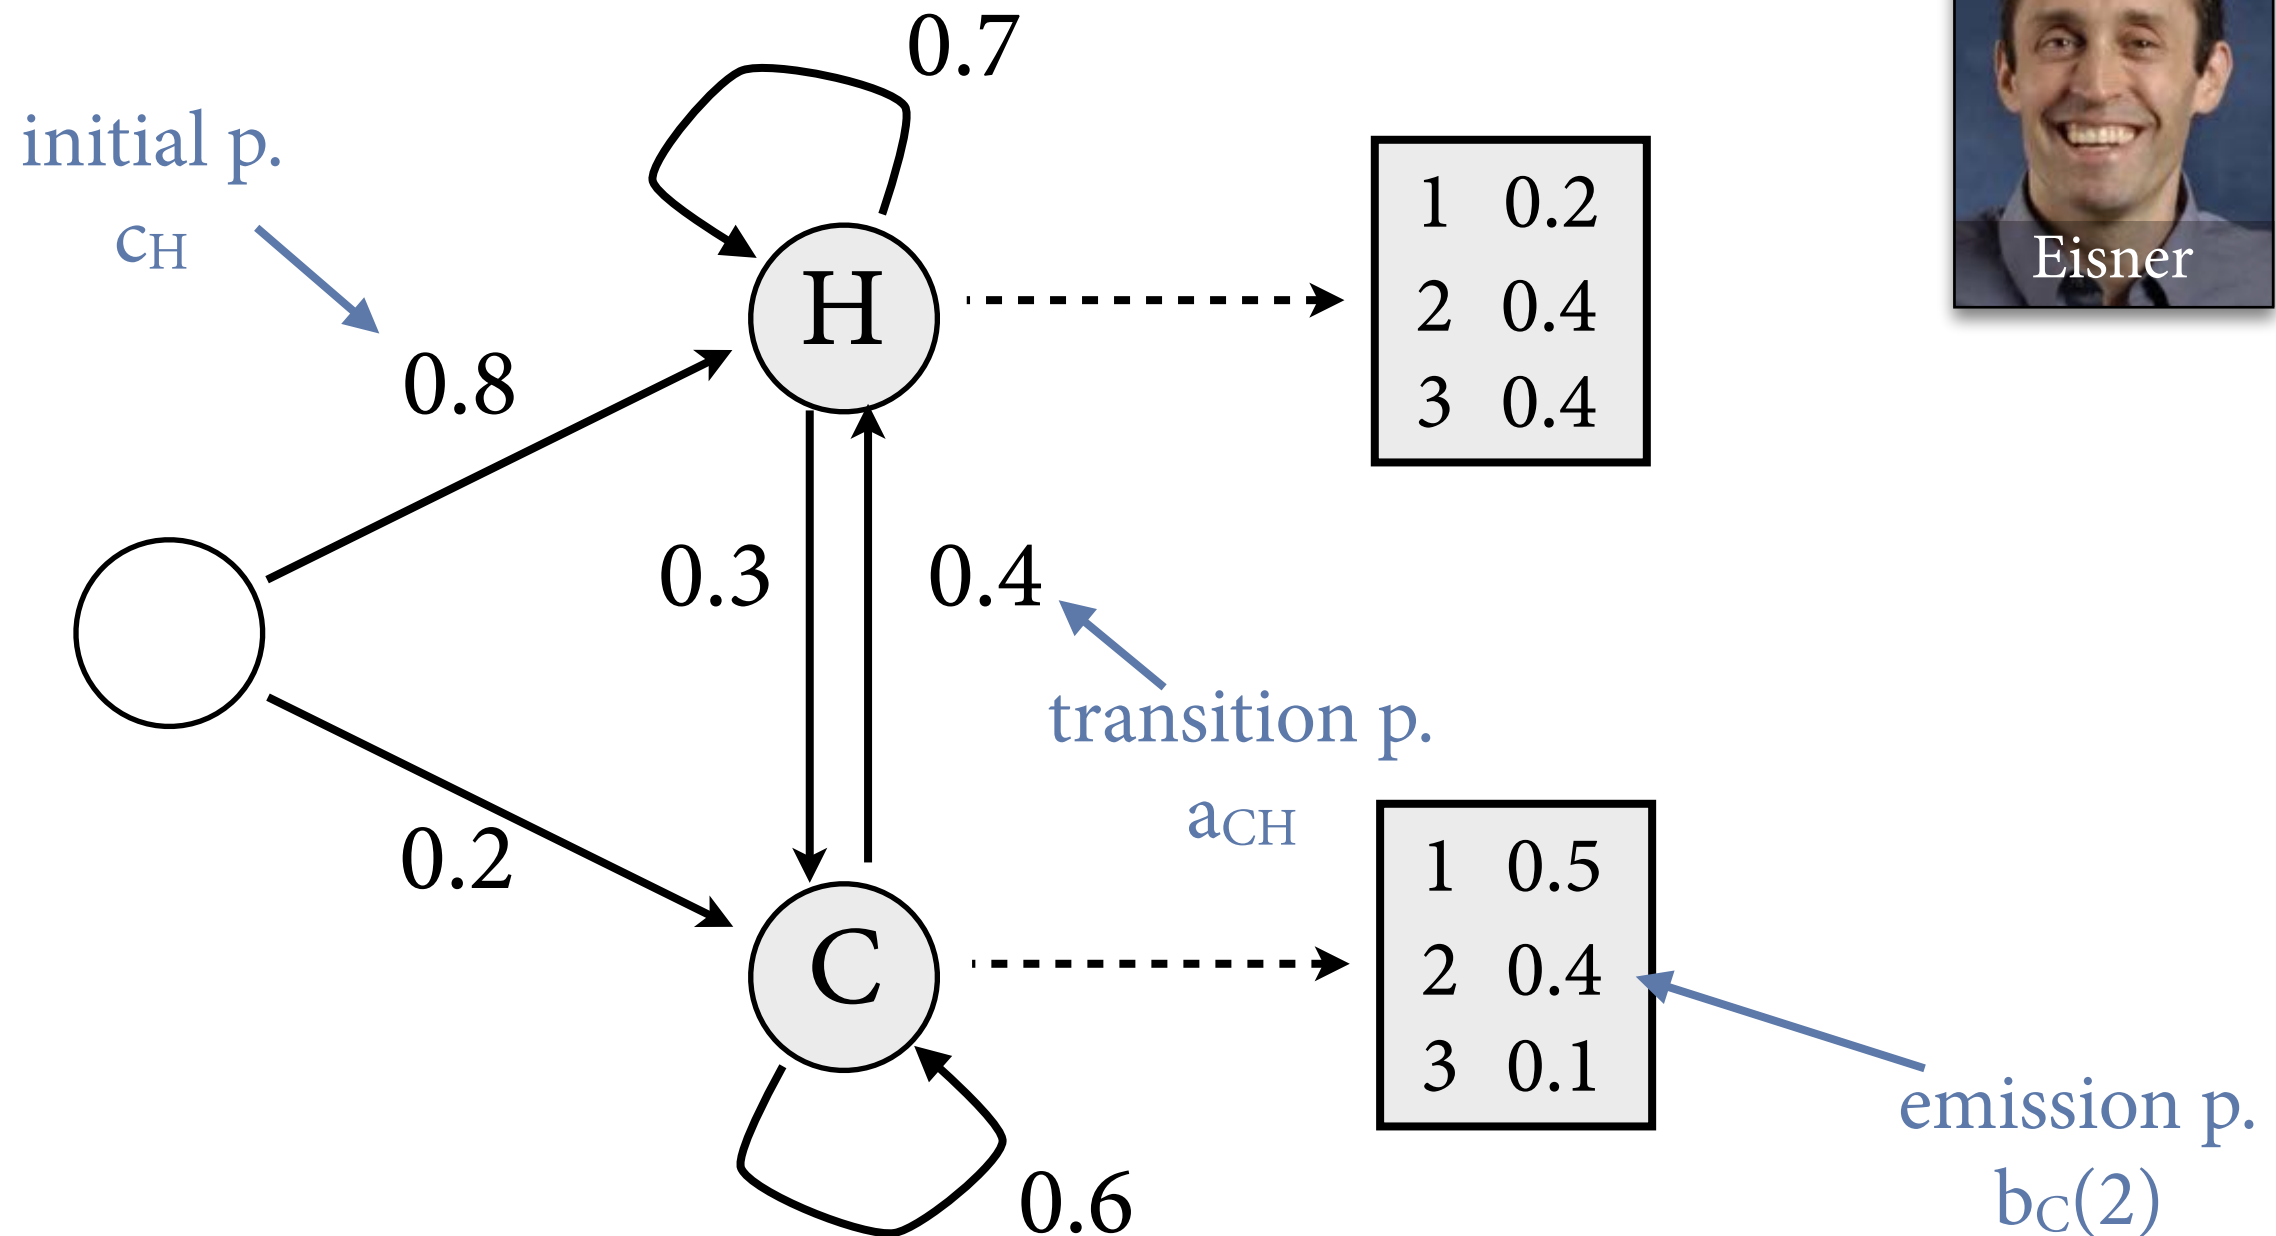

- ▶ finite set $Q = \{q_1, \dots, q_N\}$ of *states* (= POS tags)
- ▶ finite set O of possible *observations* (= words)
- ▶ *transition probabilities* $a_{ij} = P(X_{t+1} = q_j \mid X_t = q_i)$
- ▶ *initial probabilities* $c_i = P(X_1 = q_i)$
- ▶ *emission probabilities* $b_i(o) = P(Y_t = o \mid X_t = q_i)$

$$\sum_{j=1}^N a_{ij} = 1$$
$$\sum_{i=1}^N c_i = 1$$
$$\sum_{o \in O} b_i(o) = 1$$

- The HMM describes two coupled random processes:

- ▶ event $X_t = q_i$: At time t , HMM is in state q_i .
- ▶ event $Y_t = o$: At time t , HMM emits observation o .

Example: Eisner's Ice Cream

States represent weather on a given day: Hot, Cold
Outputs represent number of ice creams Jason eats that day

HMMs as joint models of x, y

- Coupled random processes of HMM directly give us model for *joint* probability $P(x, y)$ where
 - ▶ $y = y_1 \dots y_T$ sequence of observations, $y_t \in O$
 - ▶ $x = x_1 \dots x_T$ sequence of hidden states, $x_t \in Q$
- Defined as follows:

$$\begin{aligned} P(x, y) &= P(x) \cdot P(y \mid x) \\ &= P(X_1 = x_1) \cdot \prod_{t=2}^T P(X_t = x_t \mid X_1 = x_1, \dots, X_{t-1} = x_{t-1}) \\ &\quad \cdot \prod_{t=1}^T P(Y_t = y_t \mid Y_1 = y_1, \dots, Y_{t-1} = y_{t-1}, x) \\ &= P(X_1 = x_1) \cdot \prod_{t=2}^T P(X_t = x_t \mid X_{t-1} = x_{t-1}) \cdot \prod_{t=1}^T P(Y_t = y_t \mid X_t = x_t) \\ &= c_{x_1} \cdot \prod_{t=2}^T a_{x_{t-1}x_t} \cdot \prod_{t=1}^T b_{x_t}(y_t) \end{aligned}$$

Question 2: Tagging

- Given observations y_1, \dots, y_T (# ice creams), what is the most probable sequence x_1, \dots, x_T of hidden states (temperatures)?

- Maximum probability:

$$\max_{x_1, \dots, x_T} P(x_1, \dots, x_T \mid y_1, \dots, y_T)$$

- We are primarily interested in $\arg \max$:

$$\begin{aligned} & \arg \max_{x_1, \dots, x_T} P(x_1, \dots, x_T \mid y_1, \dots, y_T) \\ &= \arg \max_{x_1, \dots, x_T} \frac{P(x_1, \dots, x_T, y_1, \dots, y_T)}{P(y_1, \dots, y_T)} \\ &= \arg \max_{x_1, \dots, x_T} P(x_1, \dots, x_T, y_1, \dots, y_T) \end{aligned}$$

Naive approach

- Let's say Jason ate 3, 1, 3 ice creams. What was the most likely weather on these three days?
- Compute $\max P(x_1, 3, x_2, 1, x_3, 3)$ by maximizing over all possible state sequences.

$$\begin{array}{l} P(x_1, 3, x_2, 1, x_3, 3) \text{ is max of} \\ P(H, 3, H, 1, H, 3) \quad 0.012 \\ P(H, 3, H, 1, C, 3) \quad 0.001 \\ P(H, 3, C, 1, H, 3) \quad 0.008 \\ \dots \quad \dots \\ \underline{P(C, 3, C, 1, C, 3) \quad 0.0004} \\ = 0.012 \end{array}$$

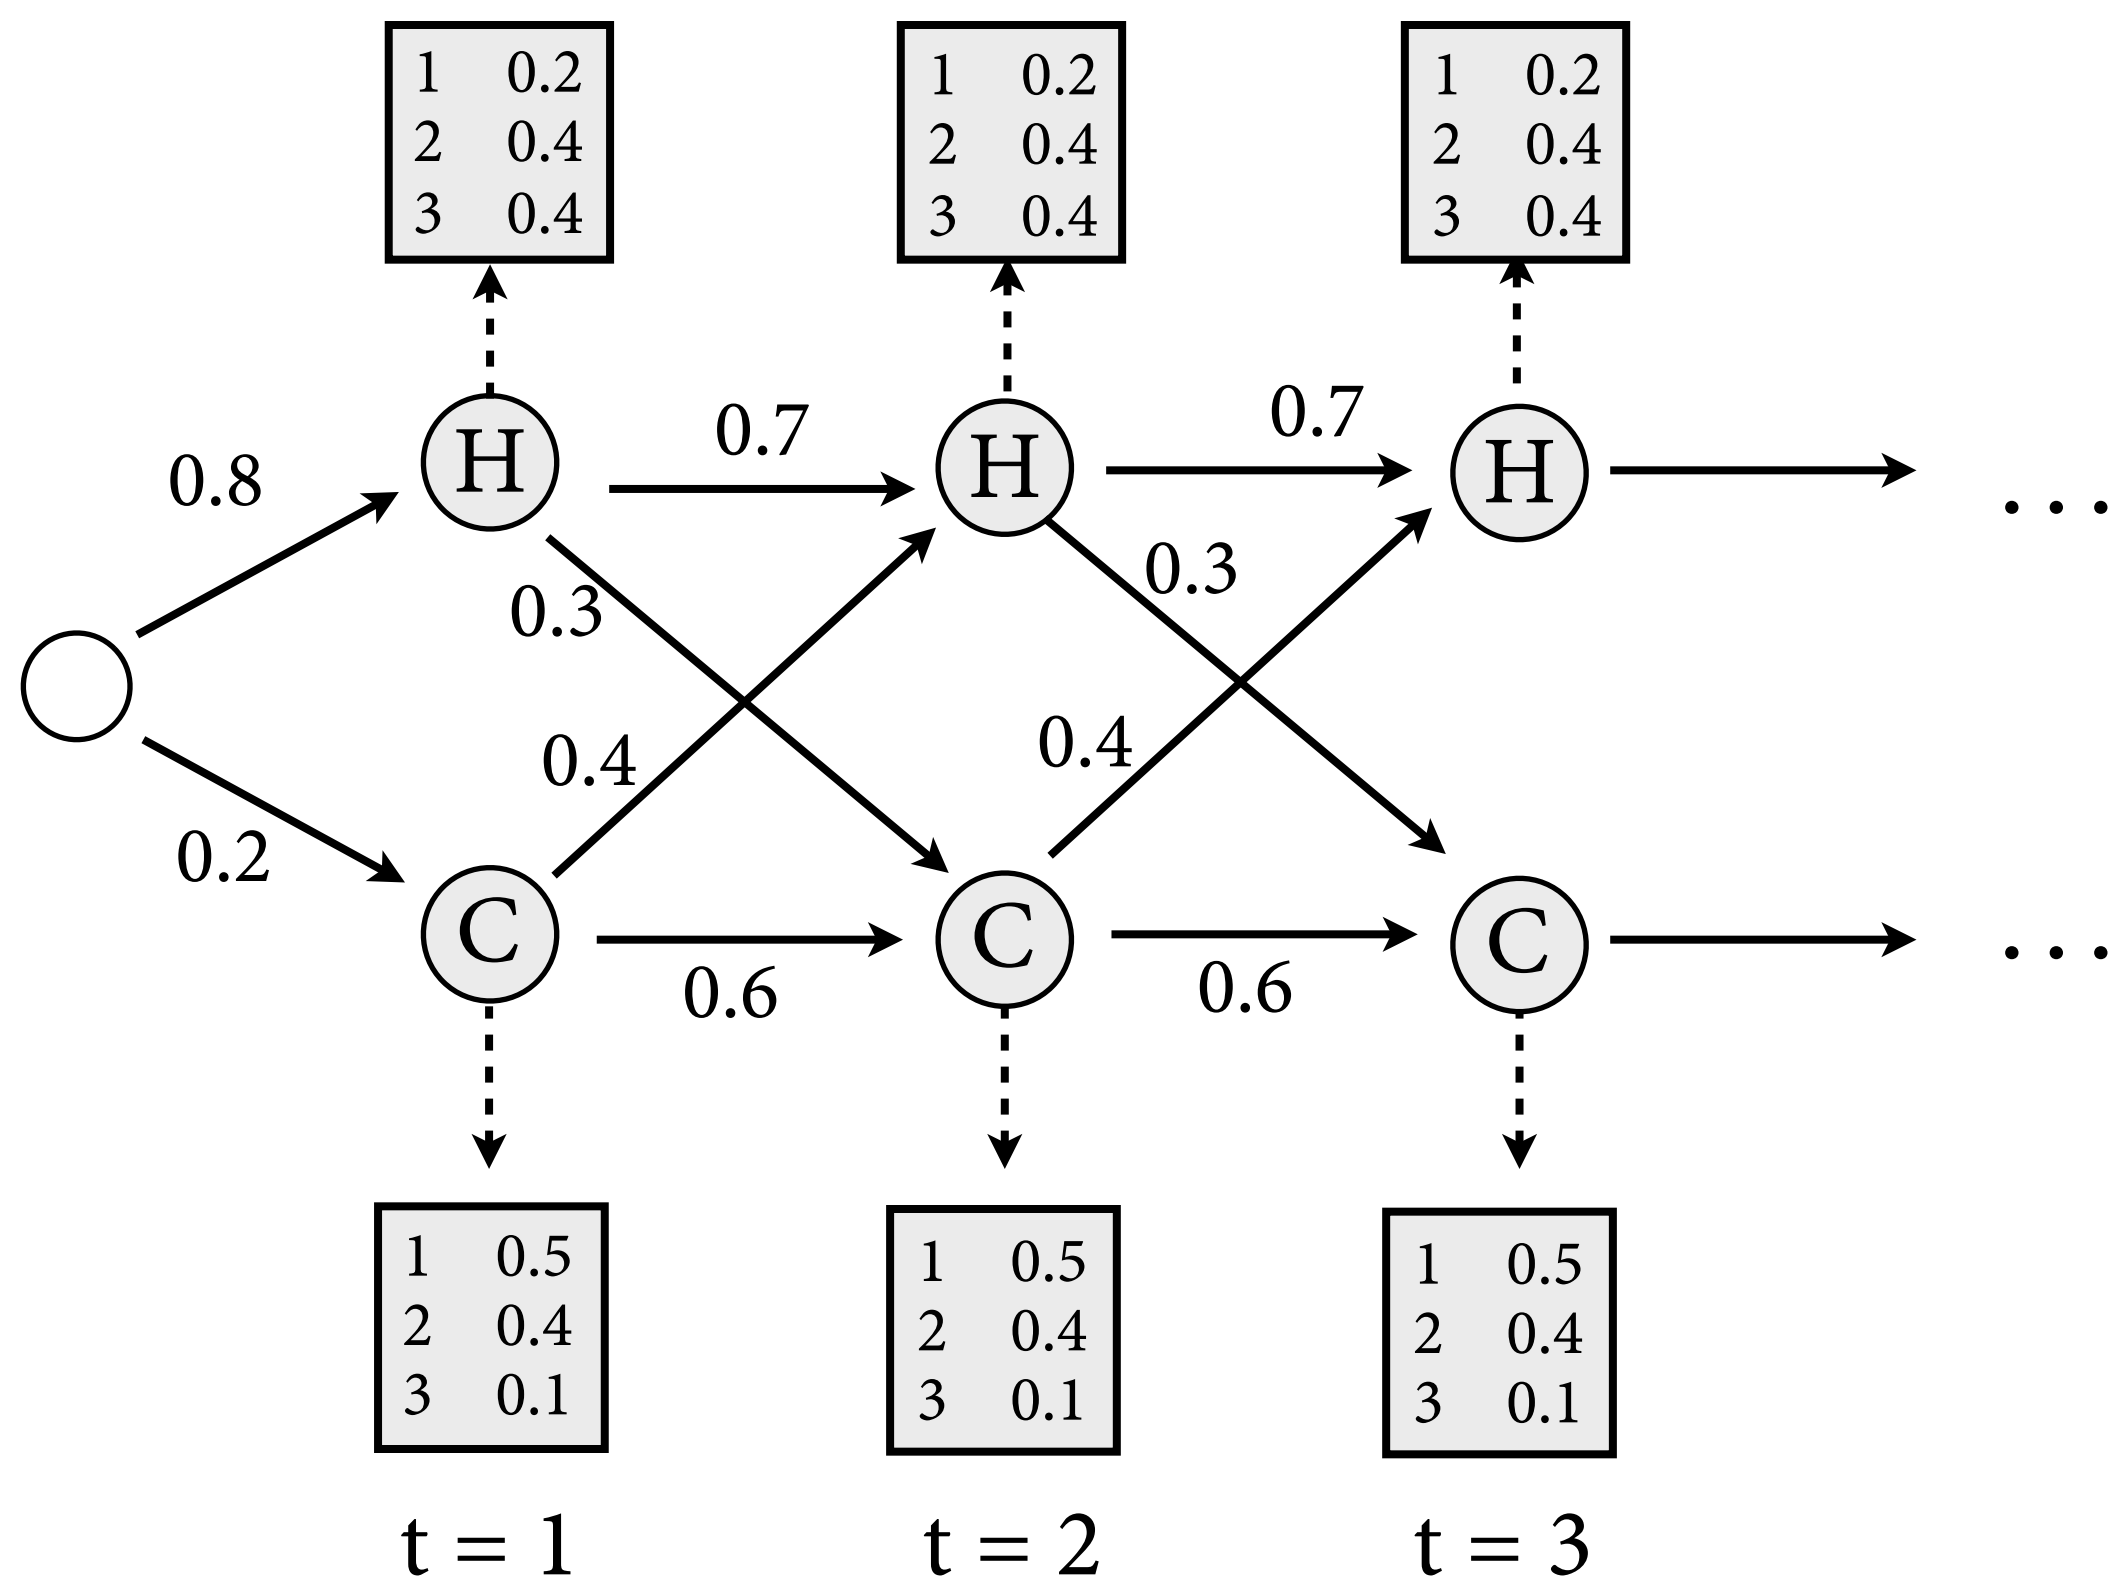

Too expensive

- Naive approach maximizes over exponentially large set of products. This is too slow for practical use.
- Visualize this in *trellis*: unfolding of HMM
 - ▶ one column for each time point t , represents X_t
 - ▶ each column contains a copy of each state of HMM
 - ▶ edges from t to $t+1$ = transitions of HMM
- Each path through trellis represents one state sequence.
 - ▶ So computation of $\max P(x,y) = \max$ over all paths.

Ice cream trellis

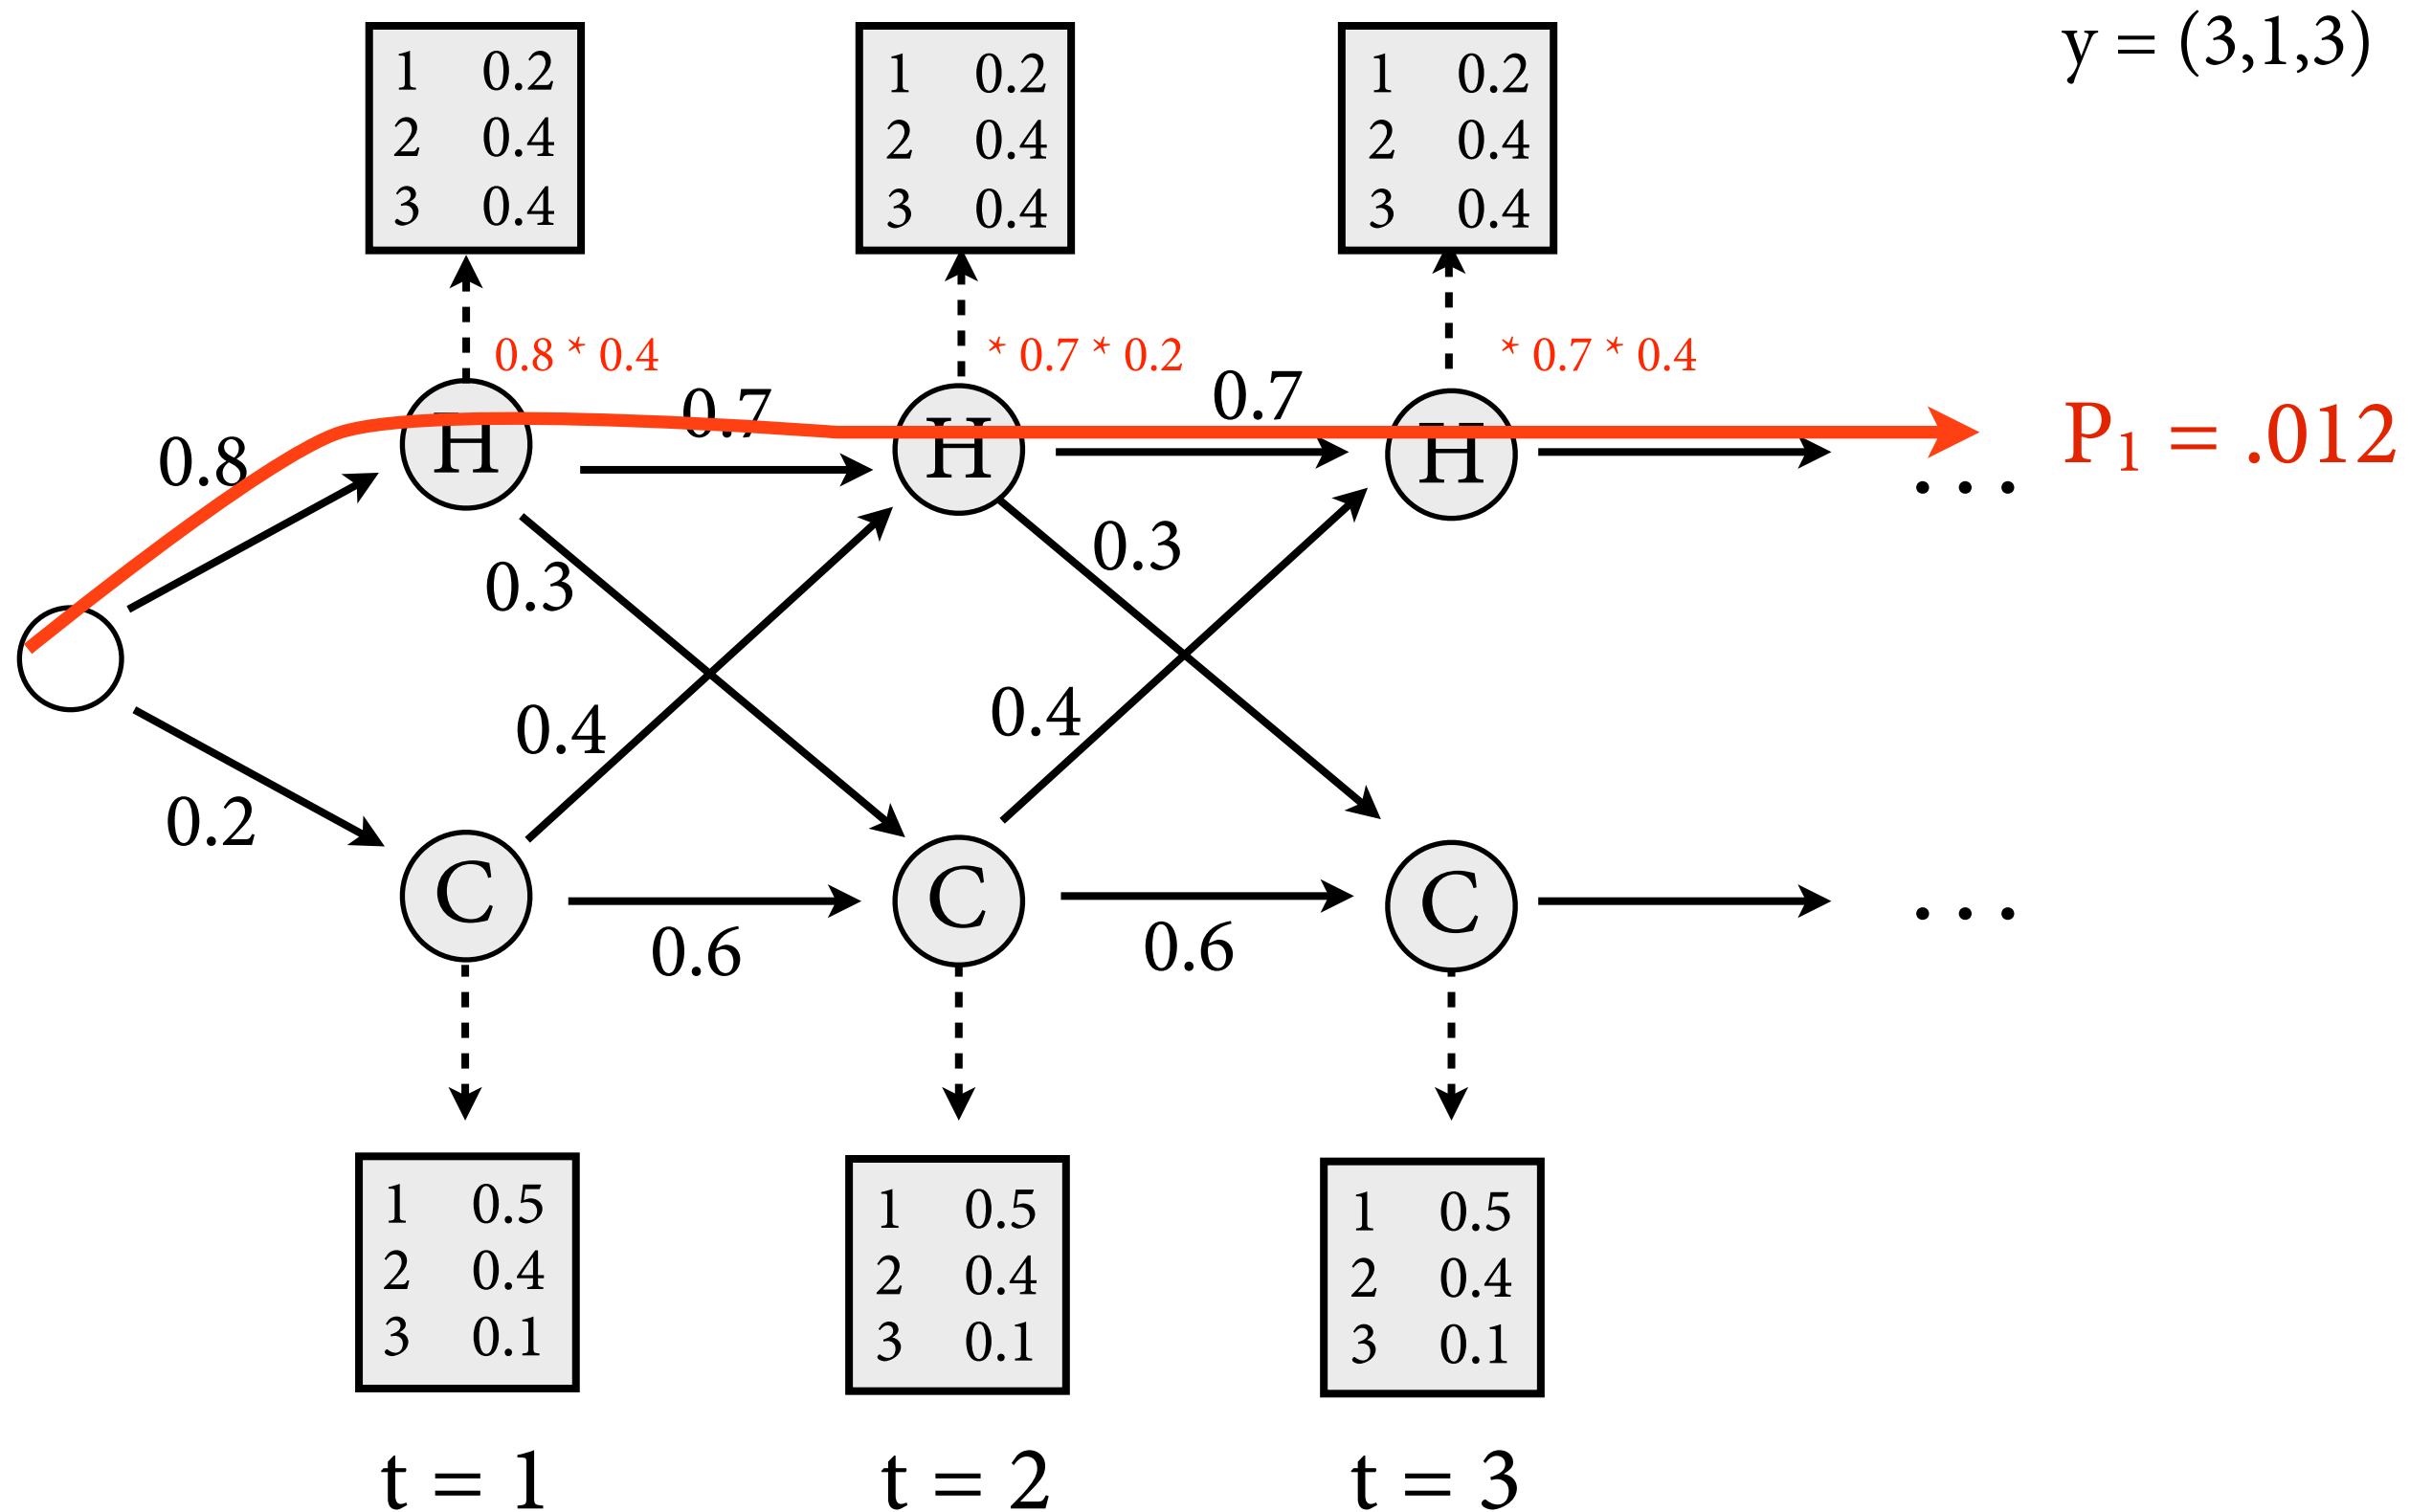

Ice cream trellis

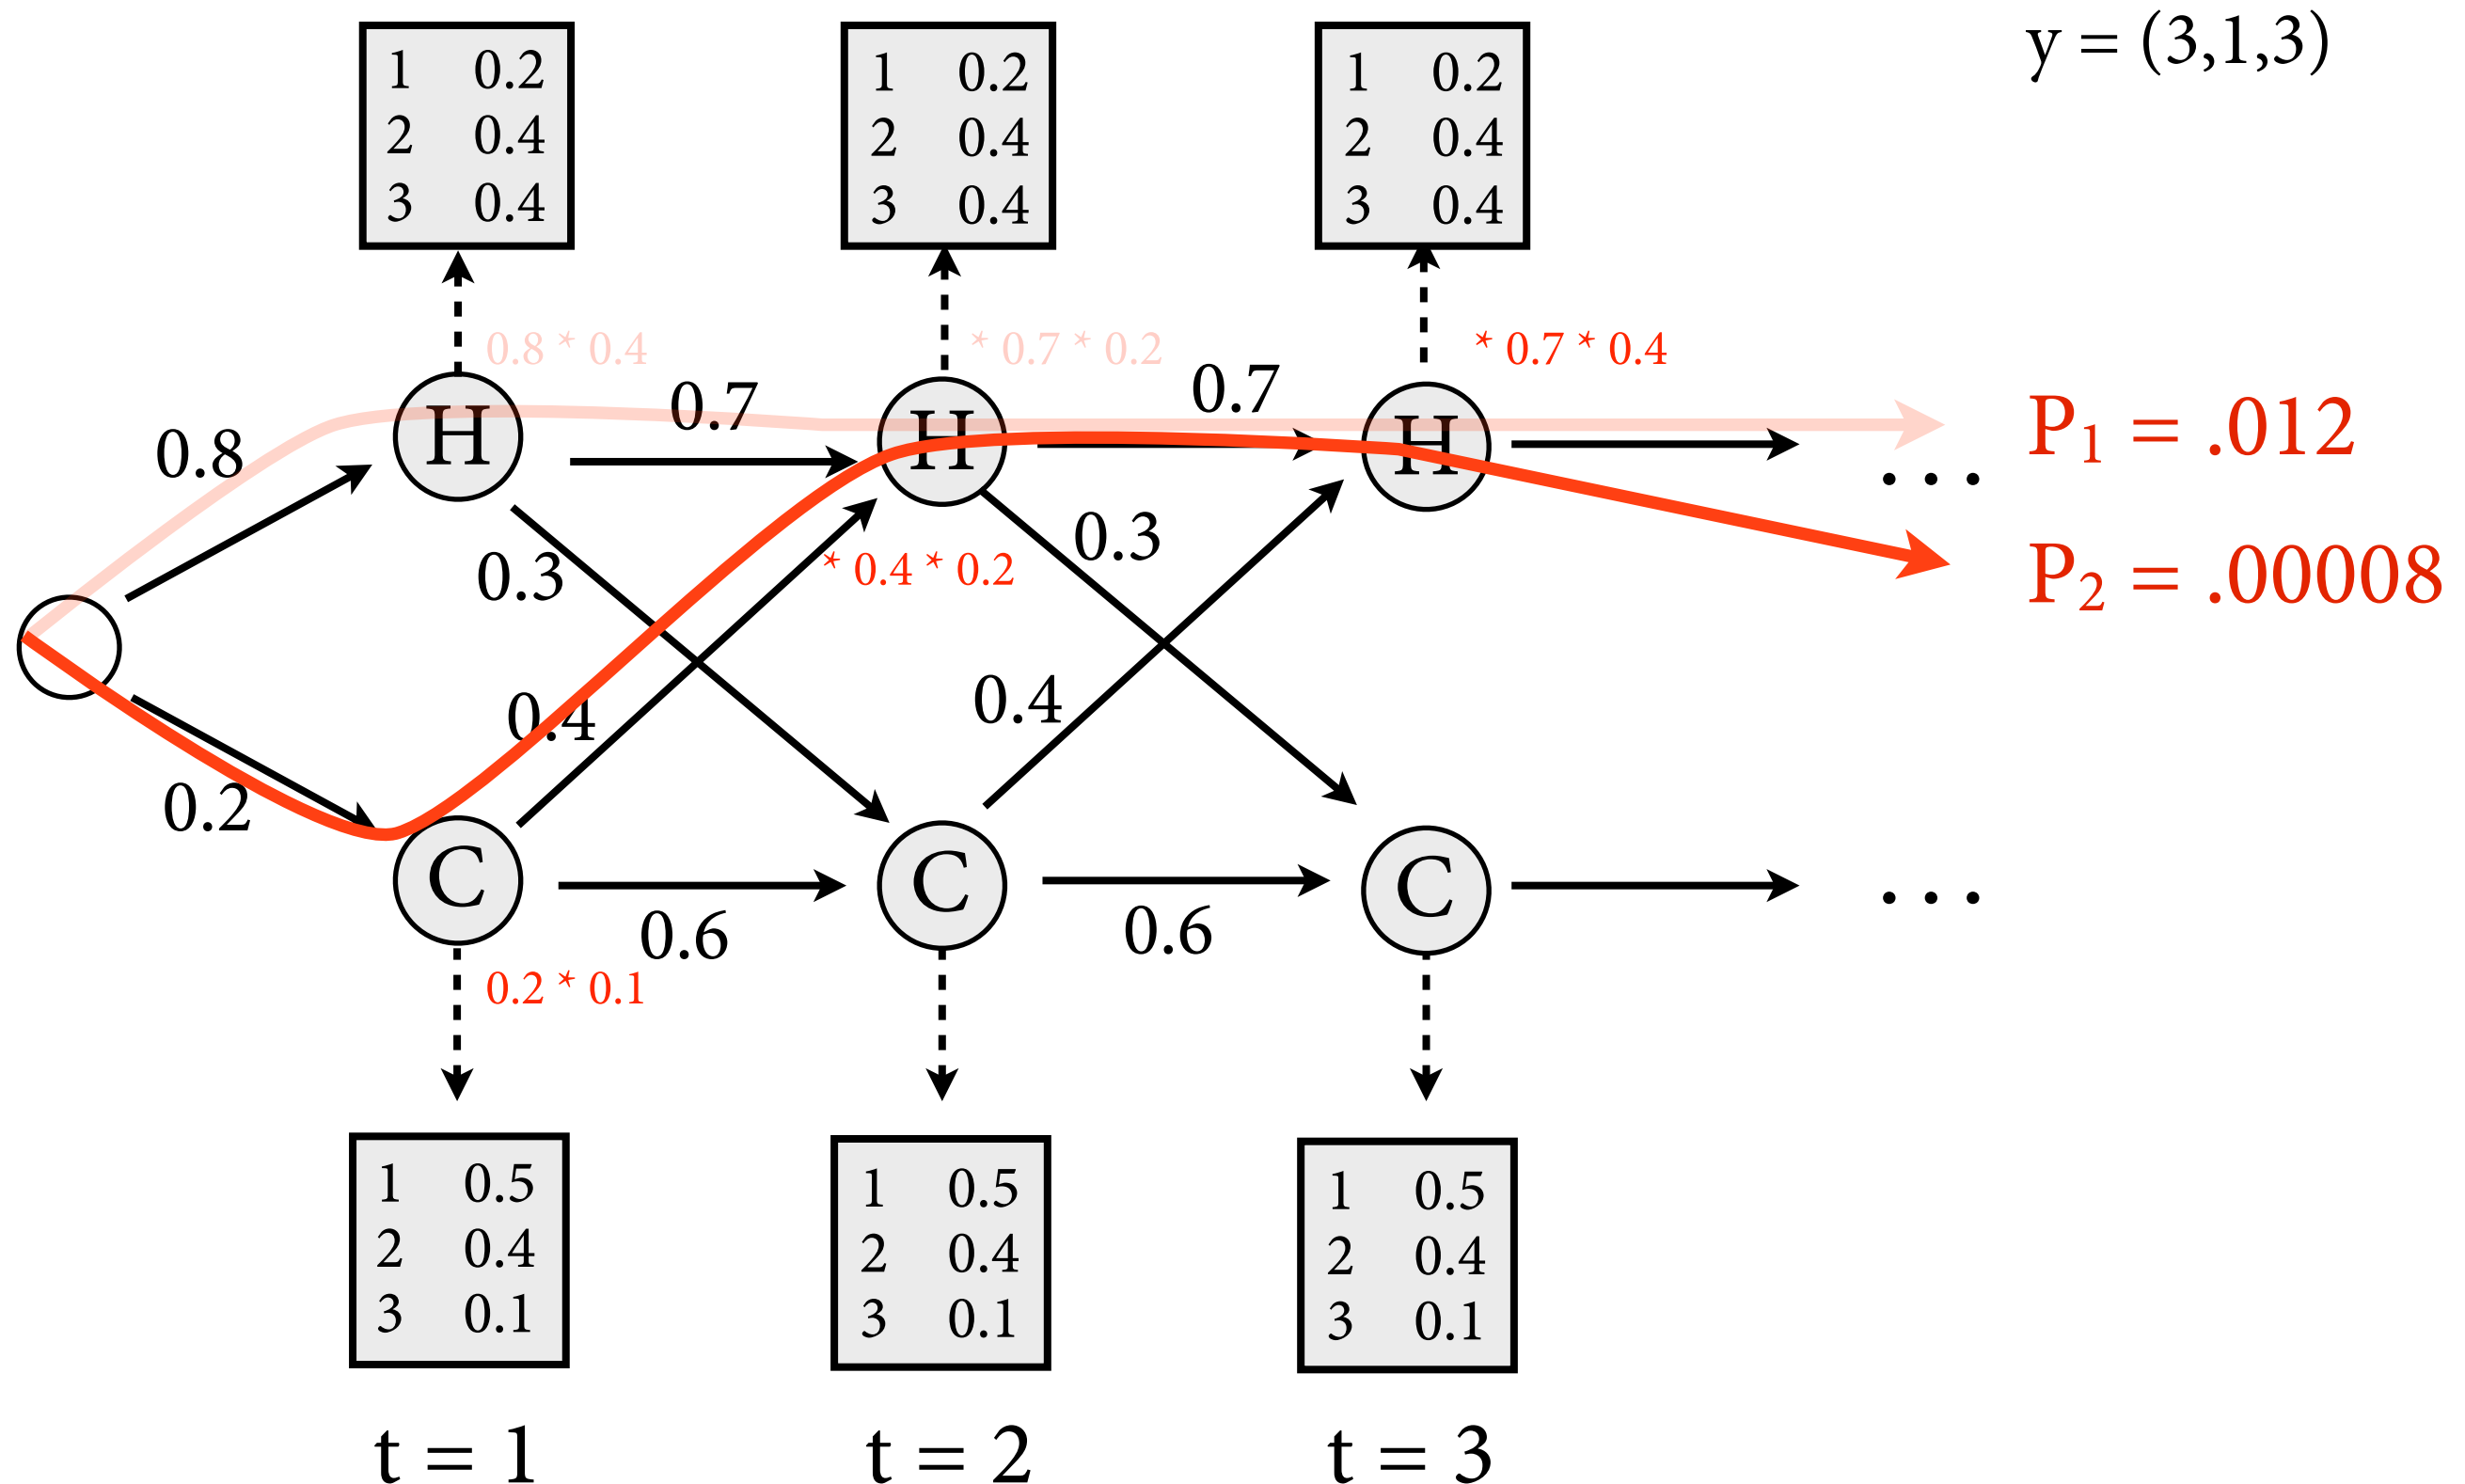

$$y = (3, 1, 3)$$

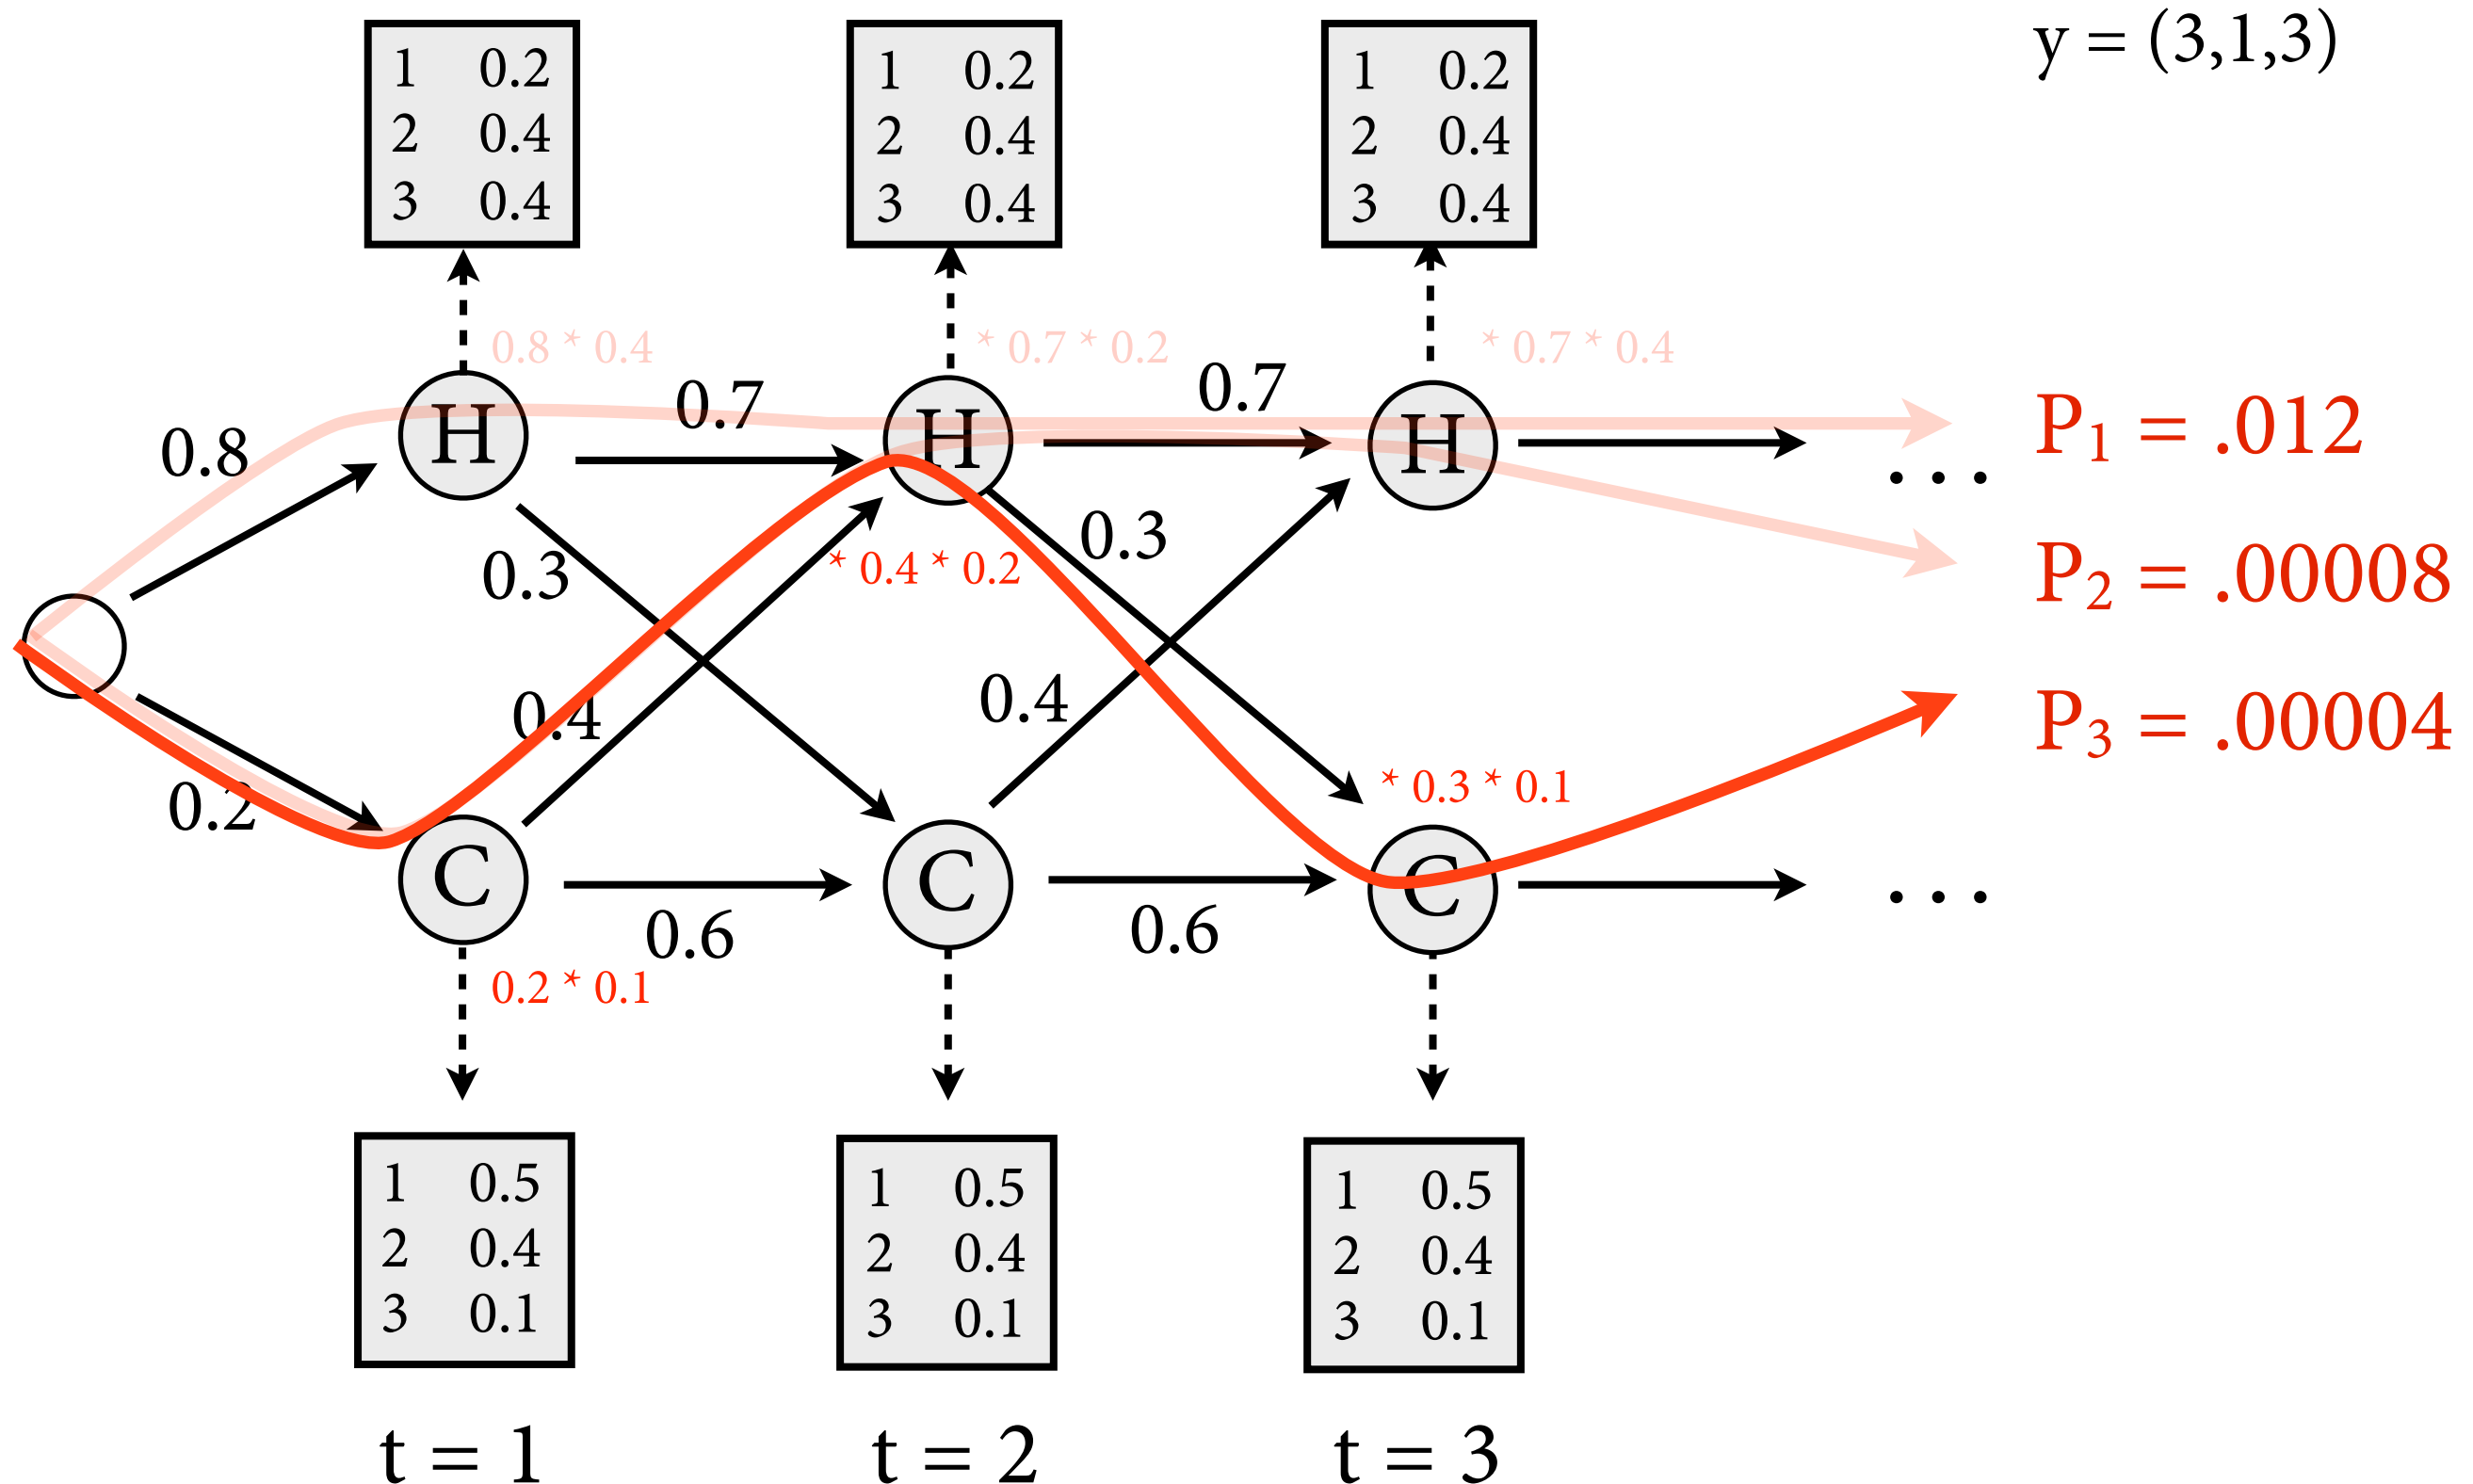

Ice cream trellis

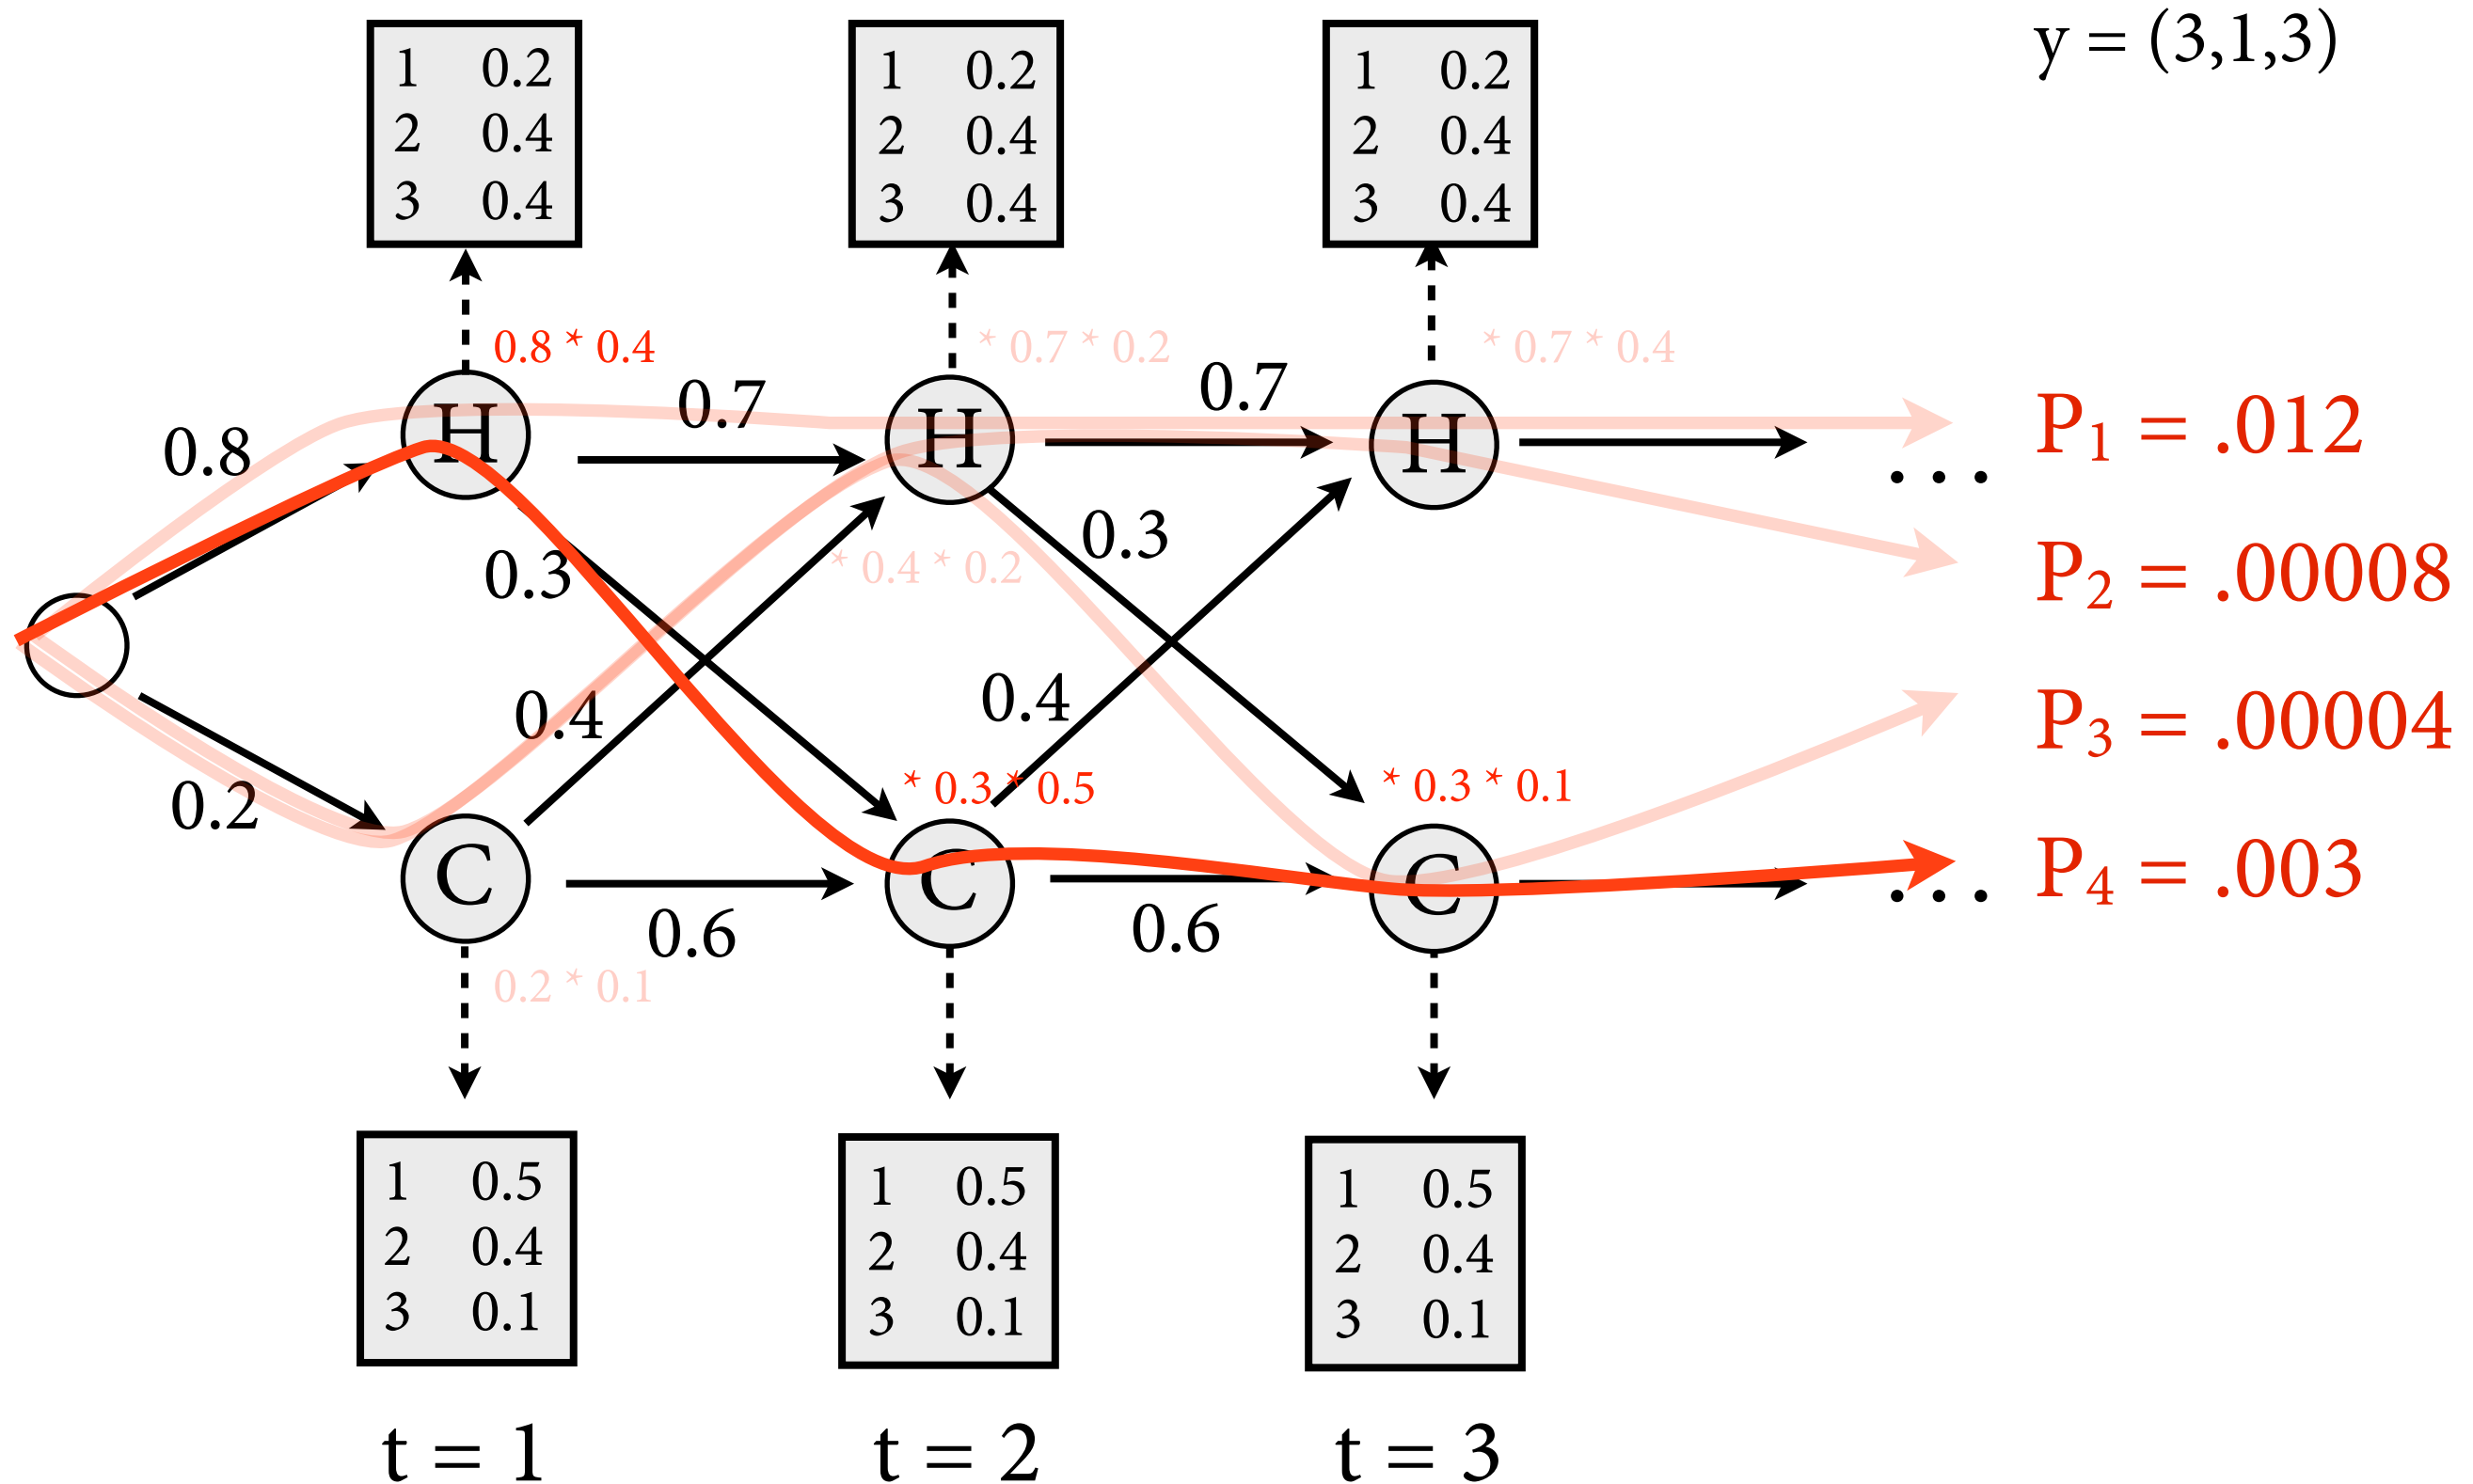

Ice cream trellis

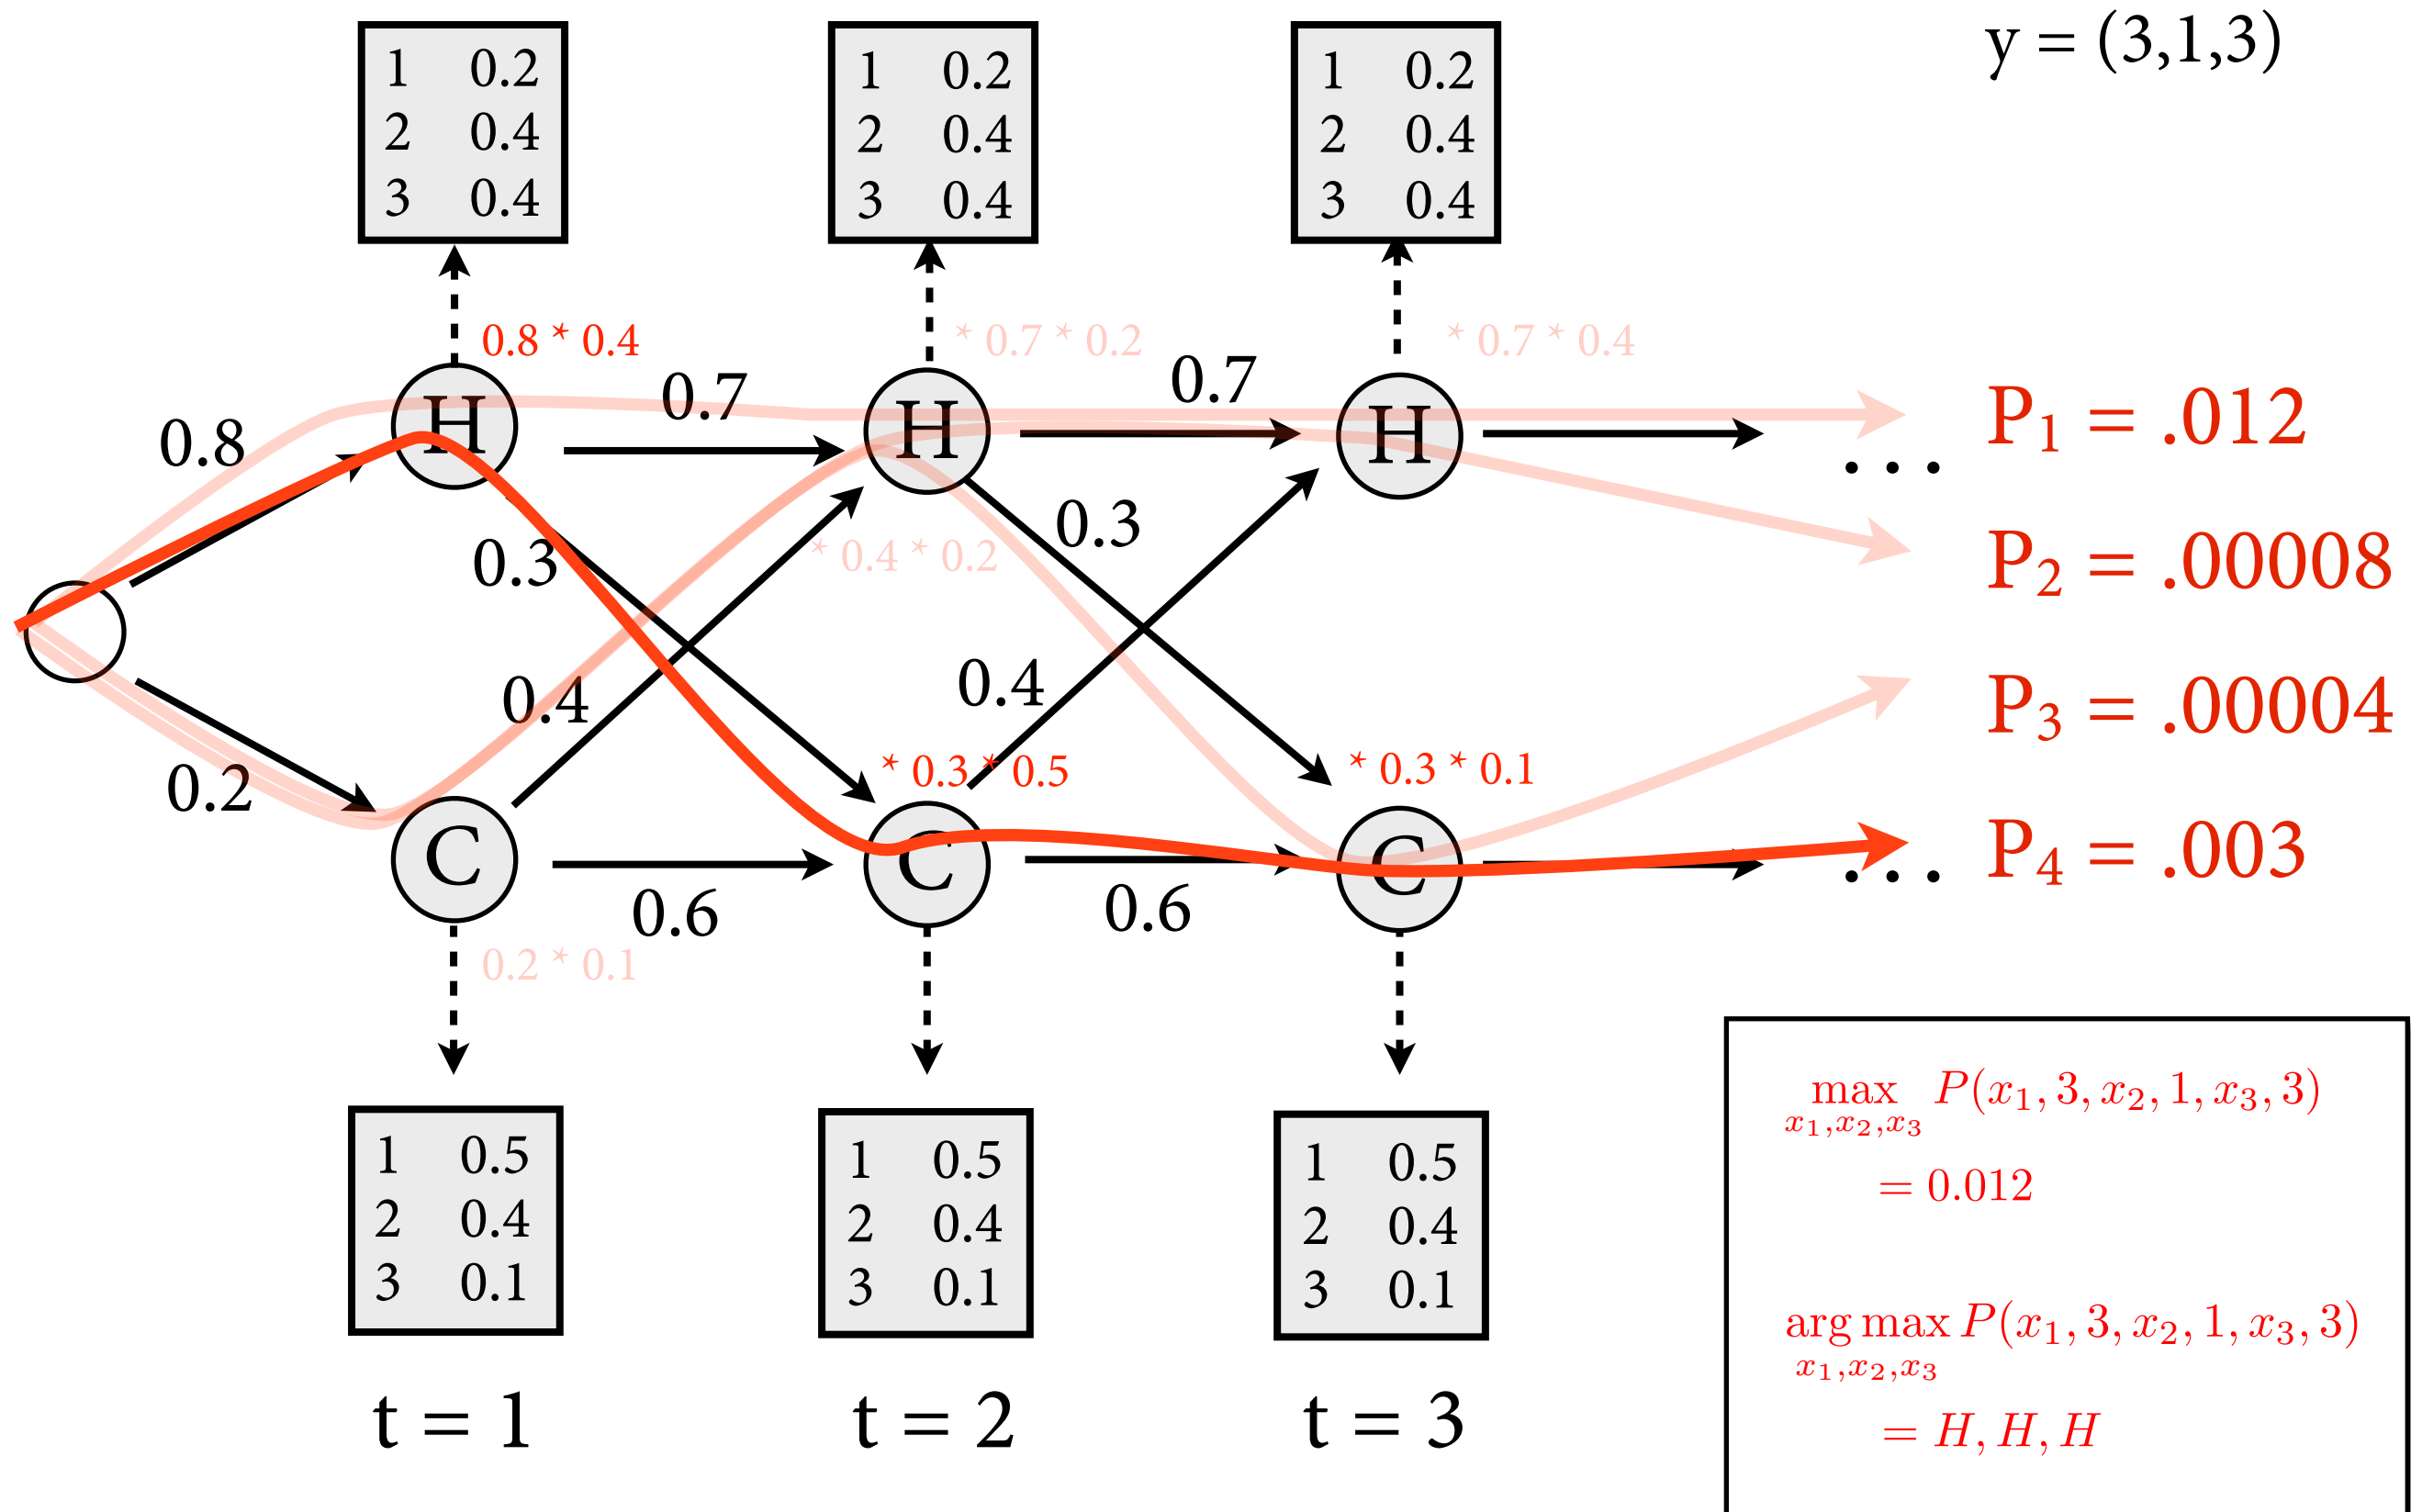

Ice cream trellis

Ice cream trellis

Ice cream trellis

Ice cream trellis

Best paths to trellis nodes

- We are trying to compute the best path through the trellis: $\arg \max_{x_1, \dots, x_T} P(X_1 = x_1, \dots, X_T = x_T, Y_1 = y_1, \dots, Y_T = y_T)$

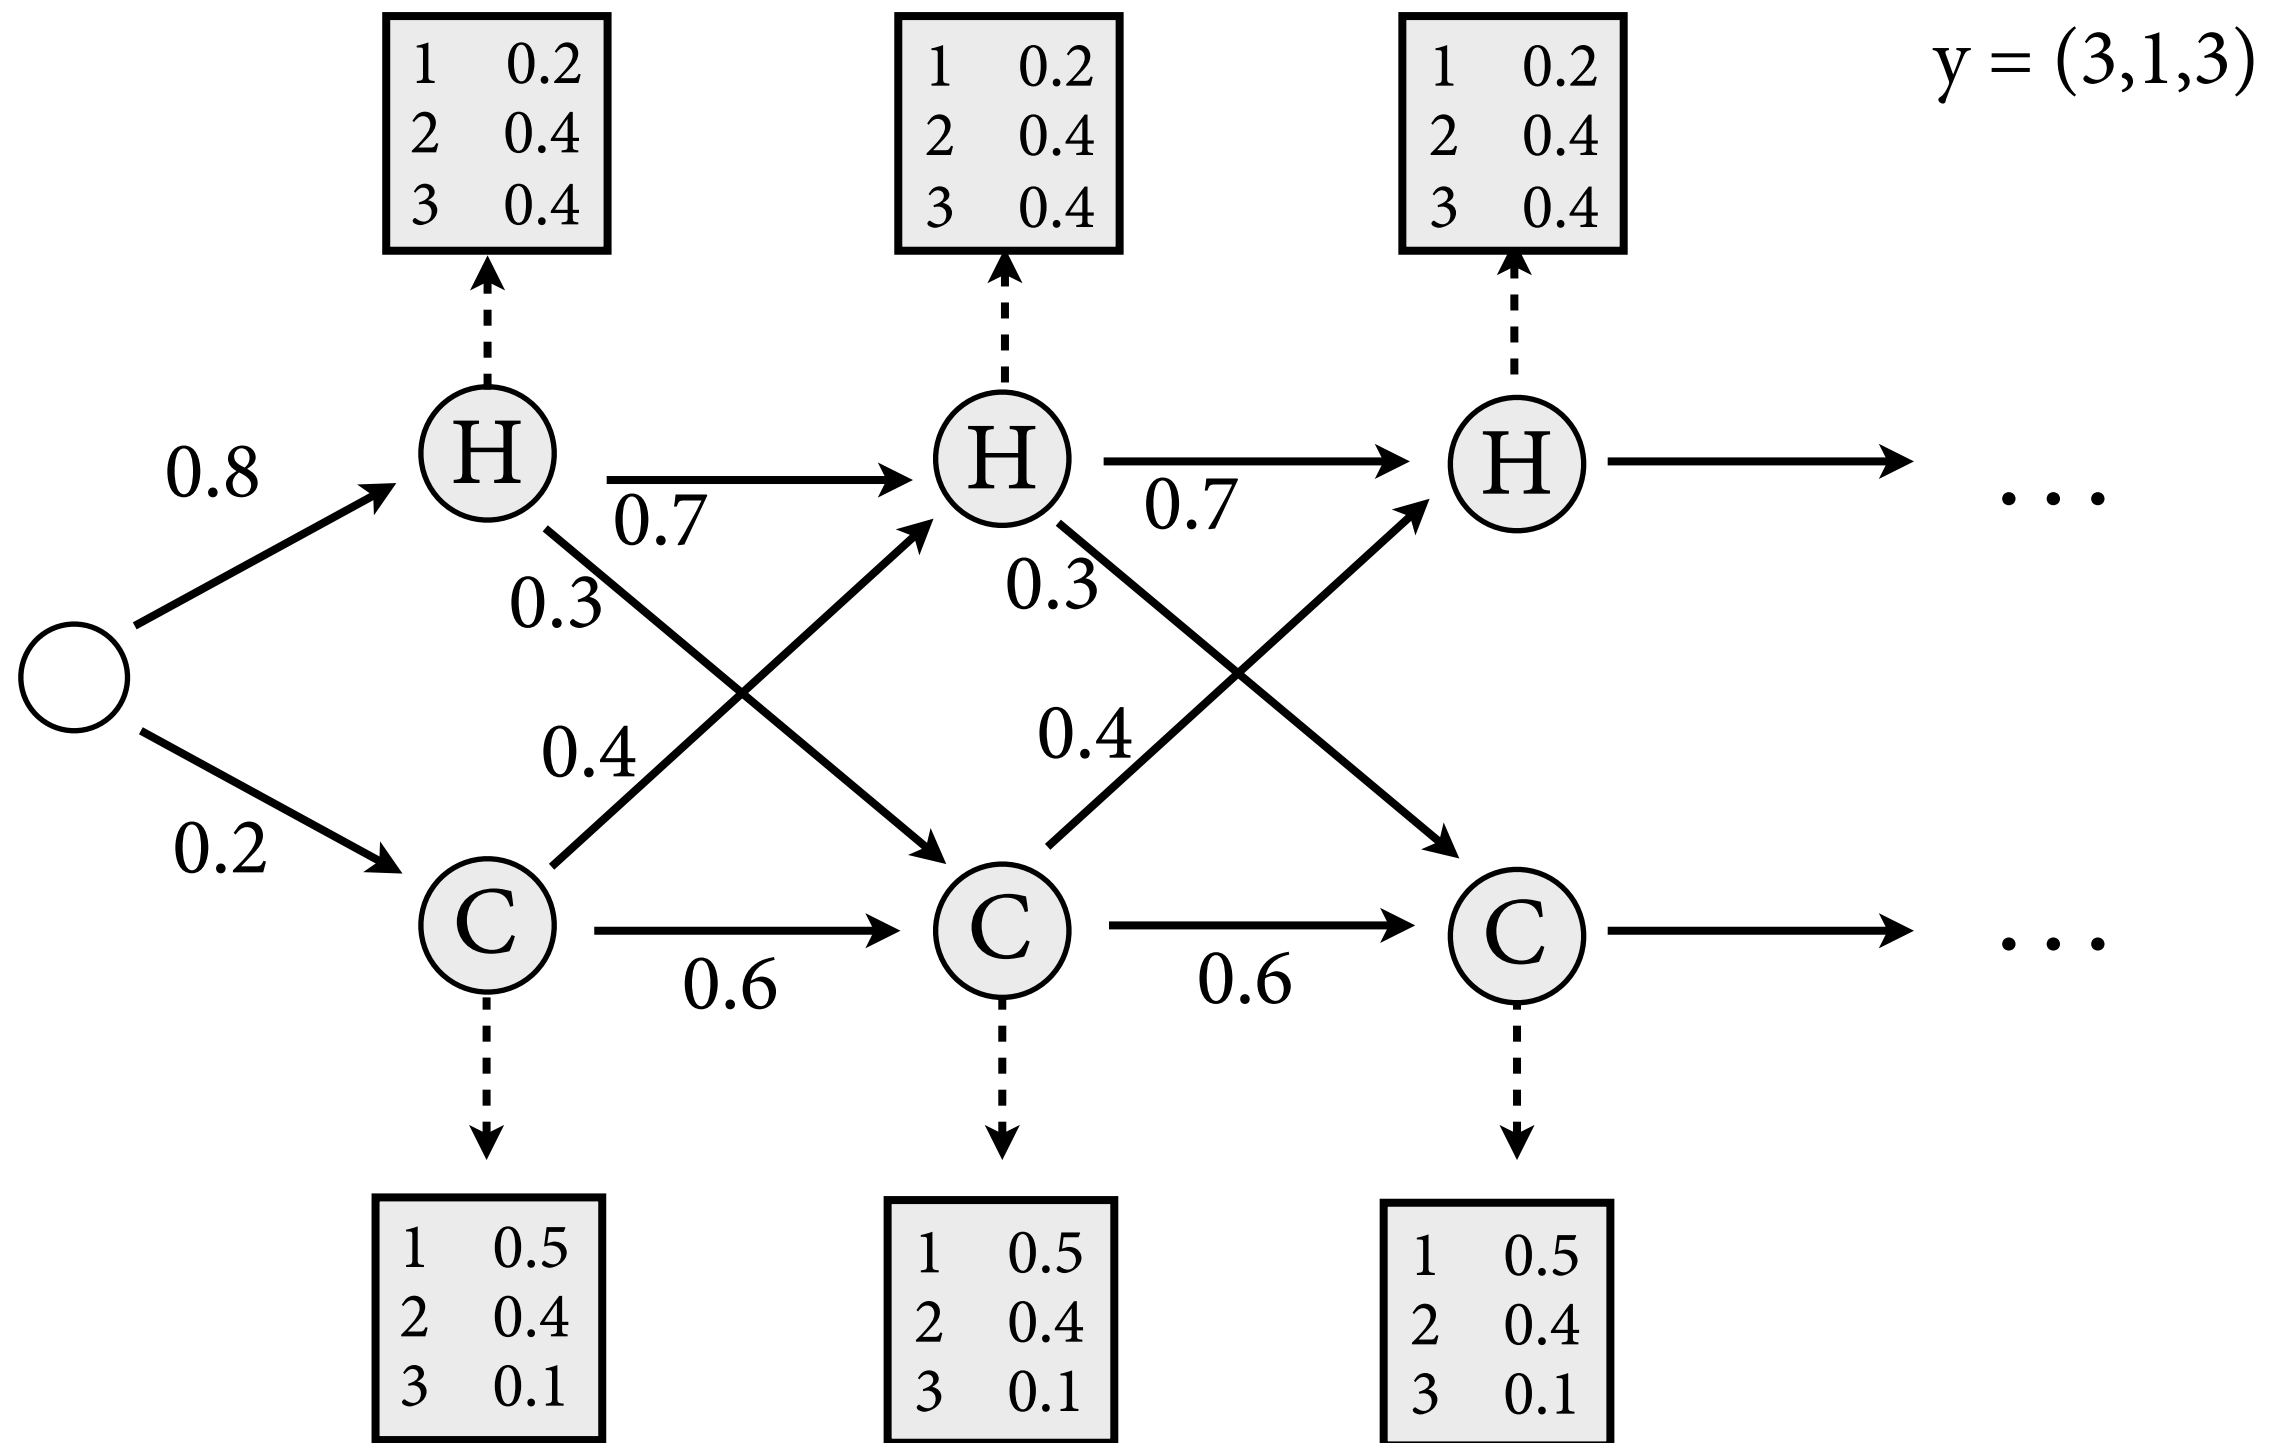

- More general concept: *best path* through the trellis that ends in a certain node $X_t = q$:

$$\arg \max_{x_1, \dots, x_{t-1}} P(X_1 = x_1, \dots, X_{t-1} = x_{t-1}, X_t = q, Y_1 = y_1, \dots, Y_t = y_t)$$

- Probability of that best path (abbreviate as $V_t(q)$):

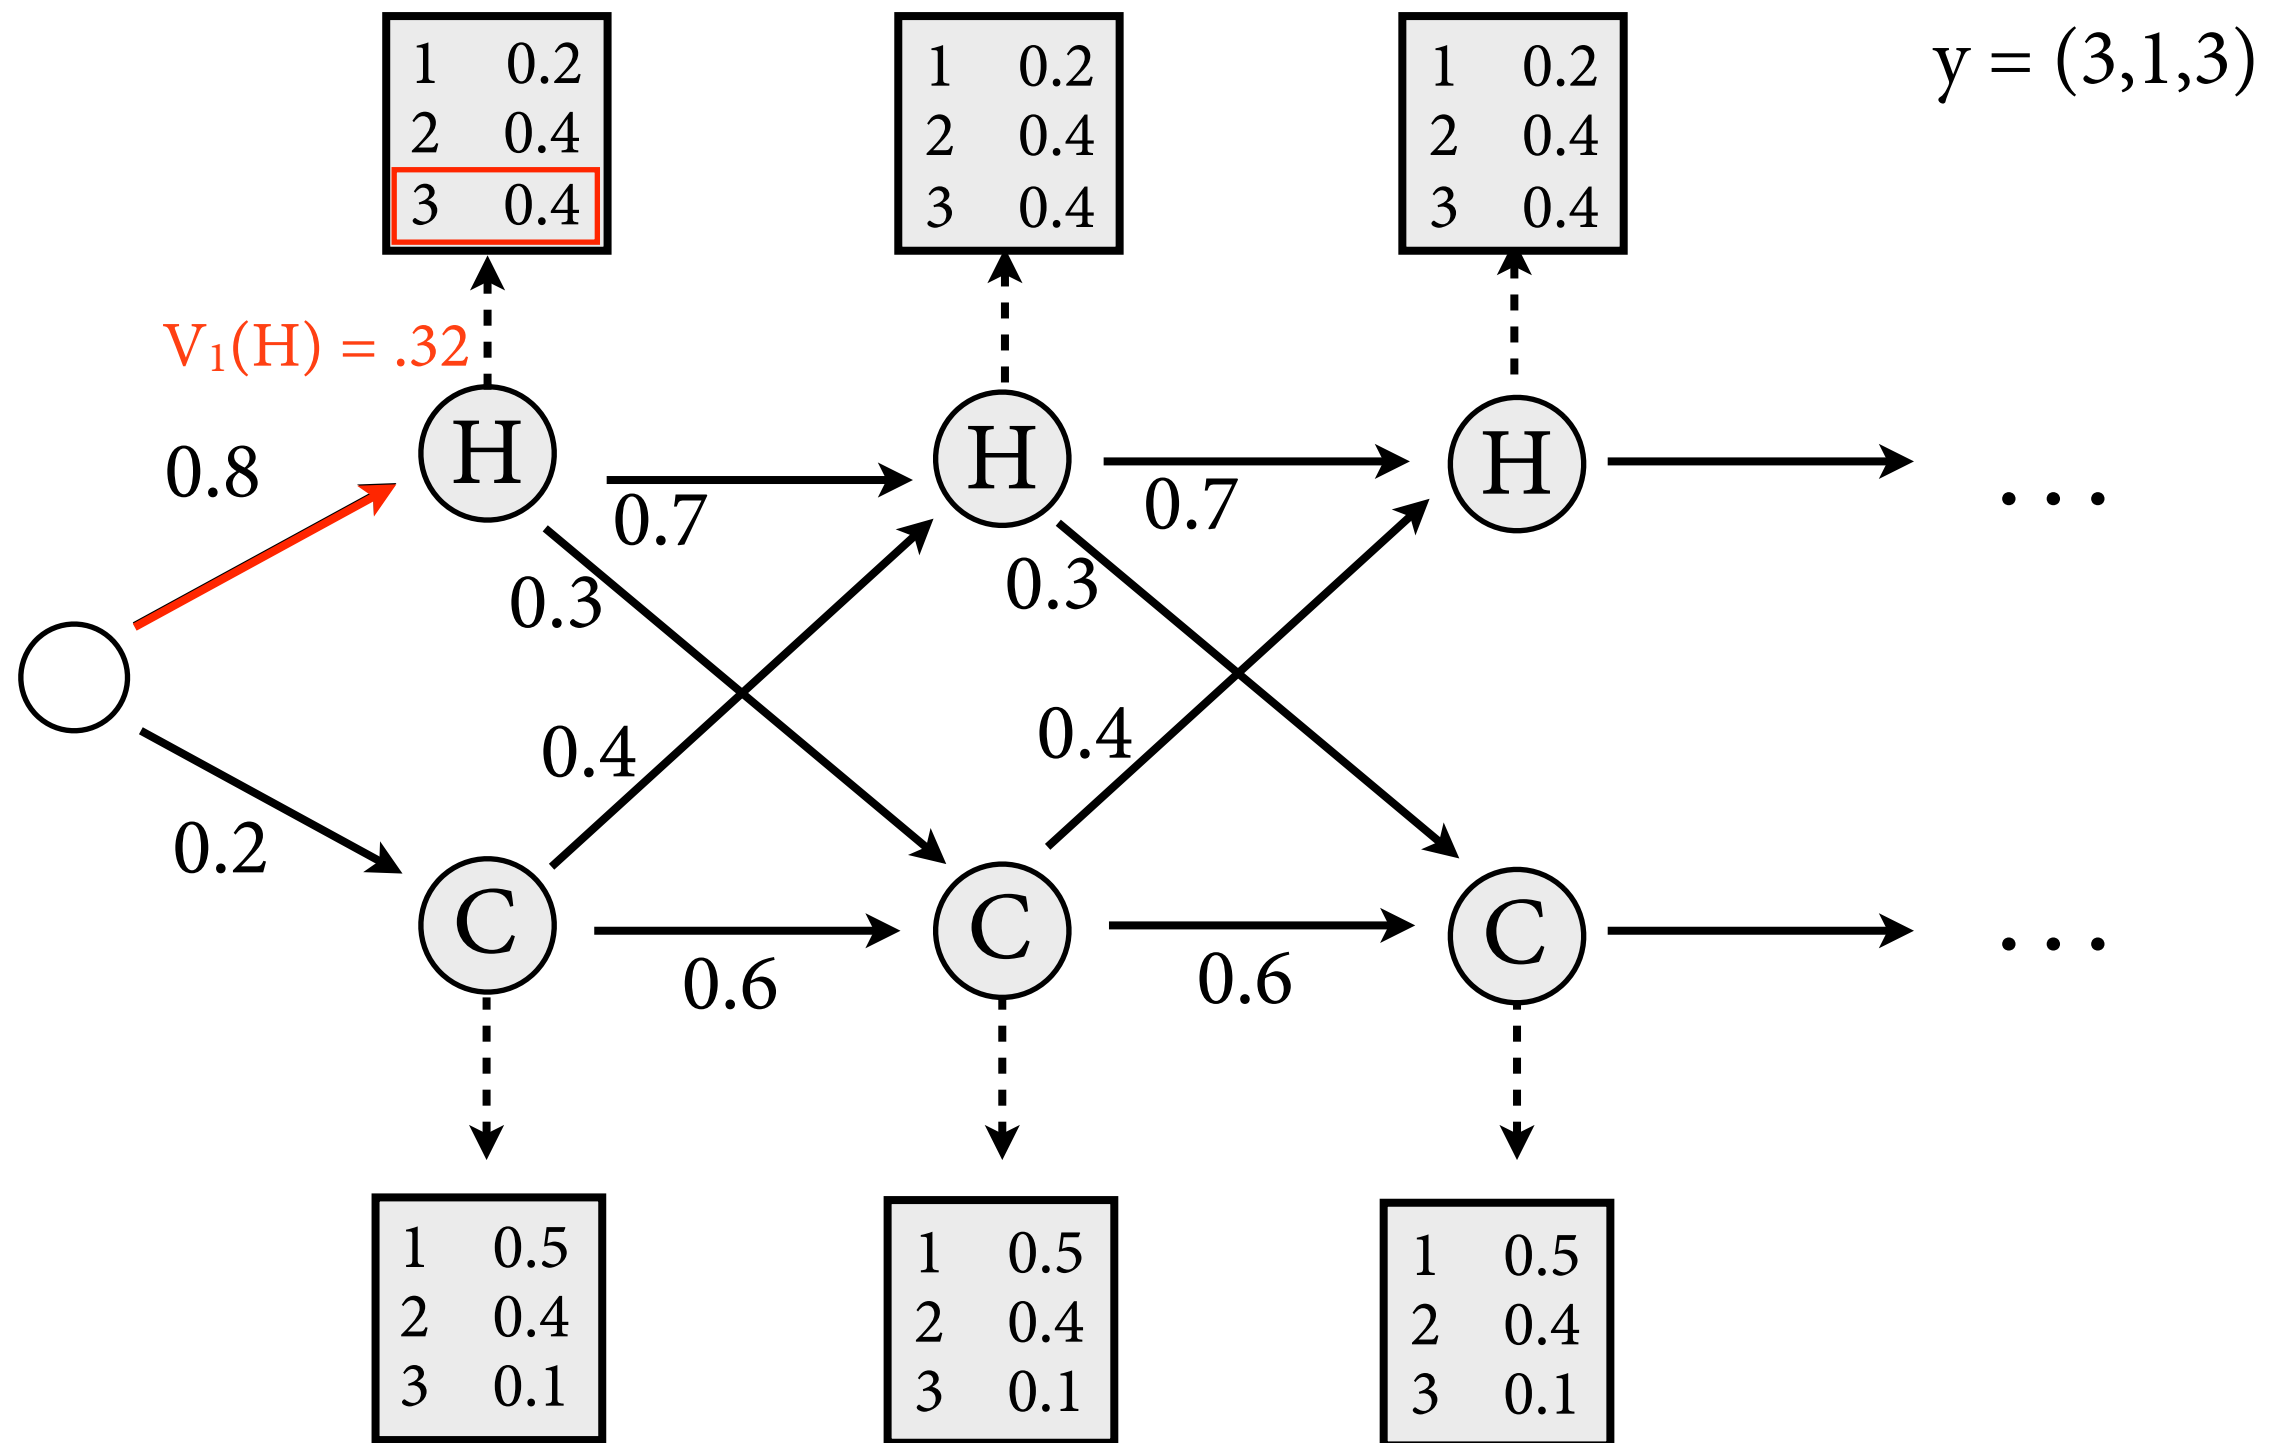

$$V_t(q) = \max_{x_1, \dots, x_{t-1}} P(X_1 = x_1, \dots, X_{t-1} = x_{t-1}, X_t = q, Y_1 = y_1, \dots, Y_t = y_t)$$

Computing best path probs

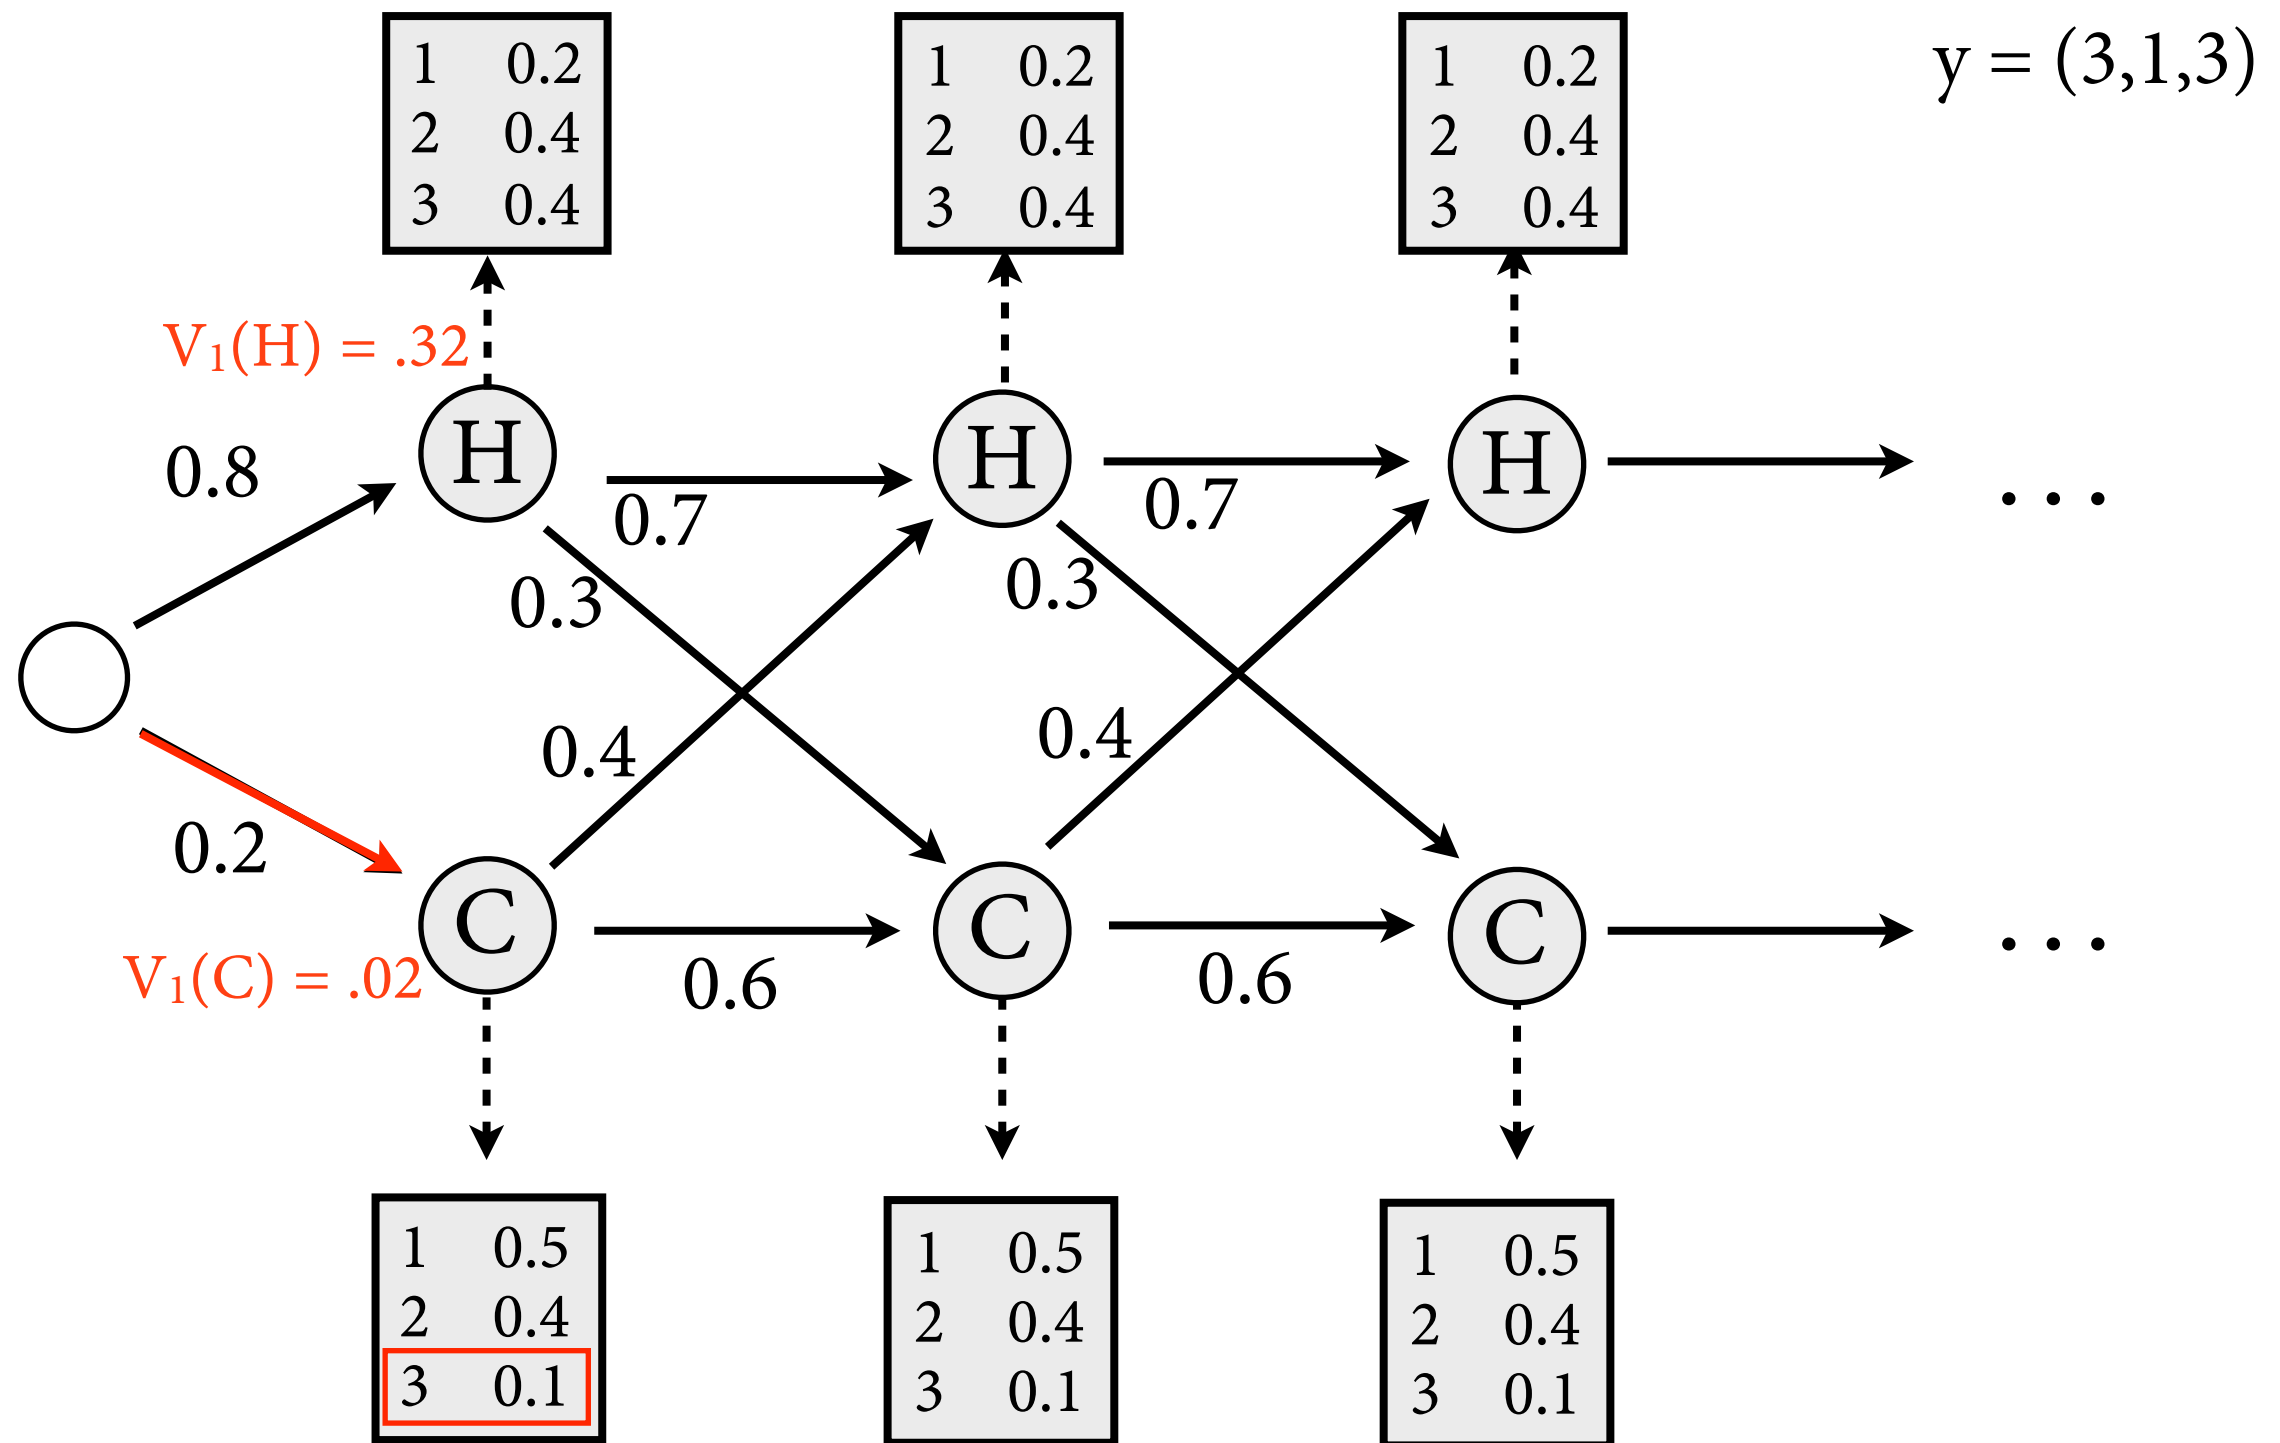

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

Computing best path probs

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

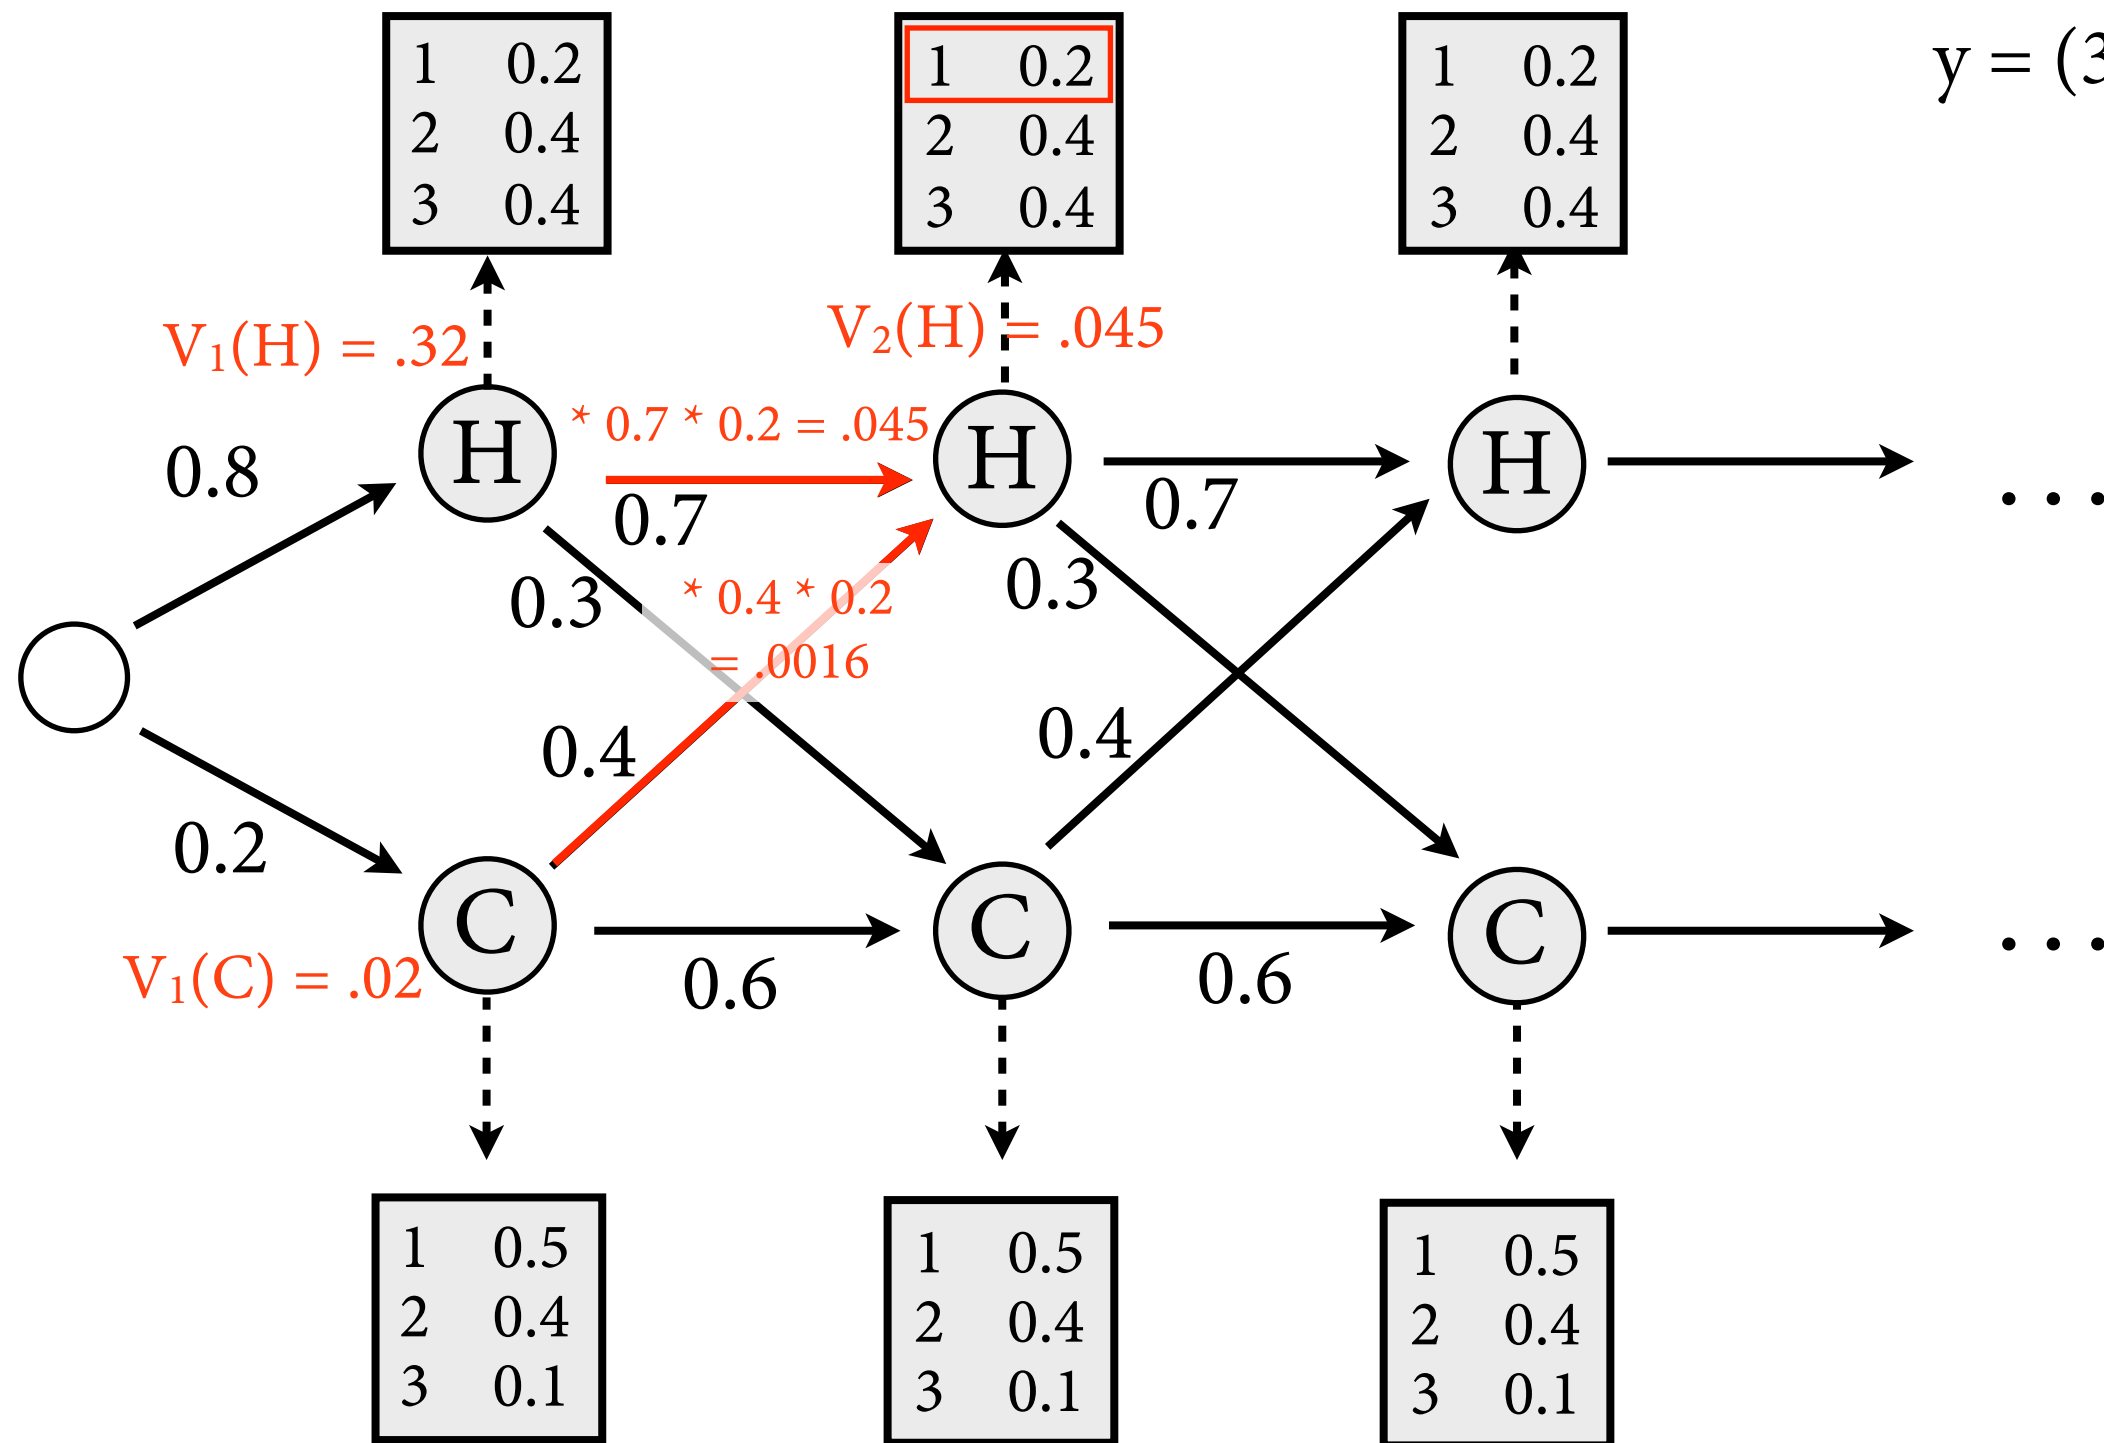

Computing best path probs

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

Computing best path probs

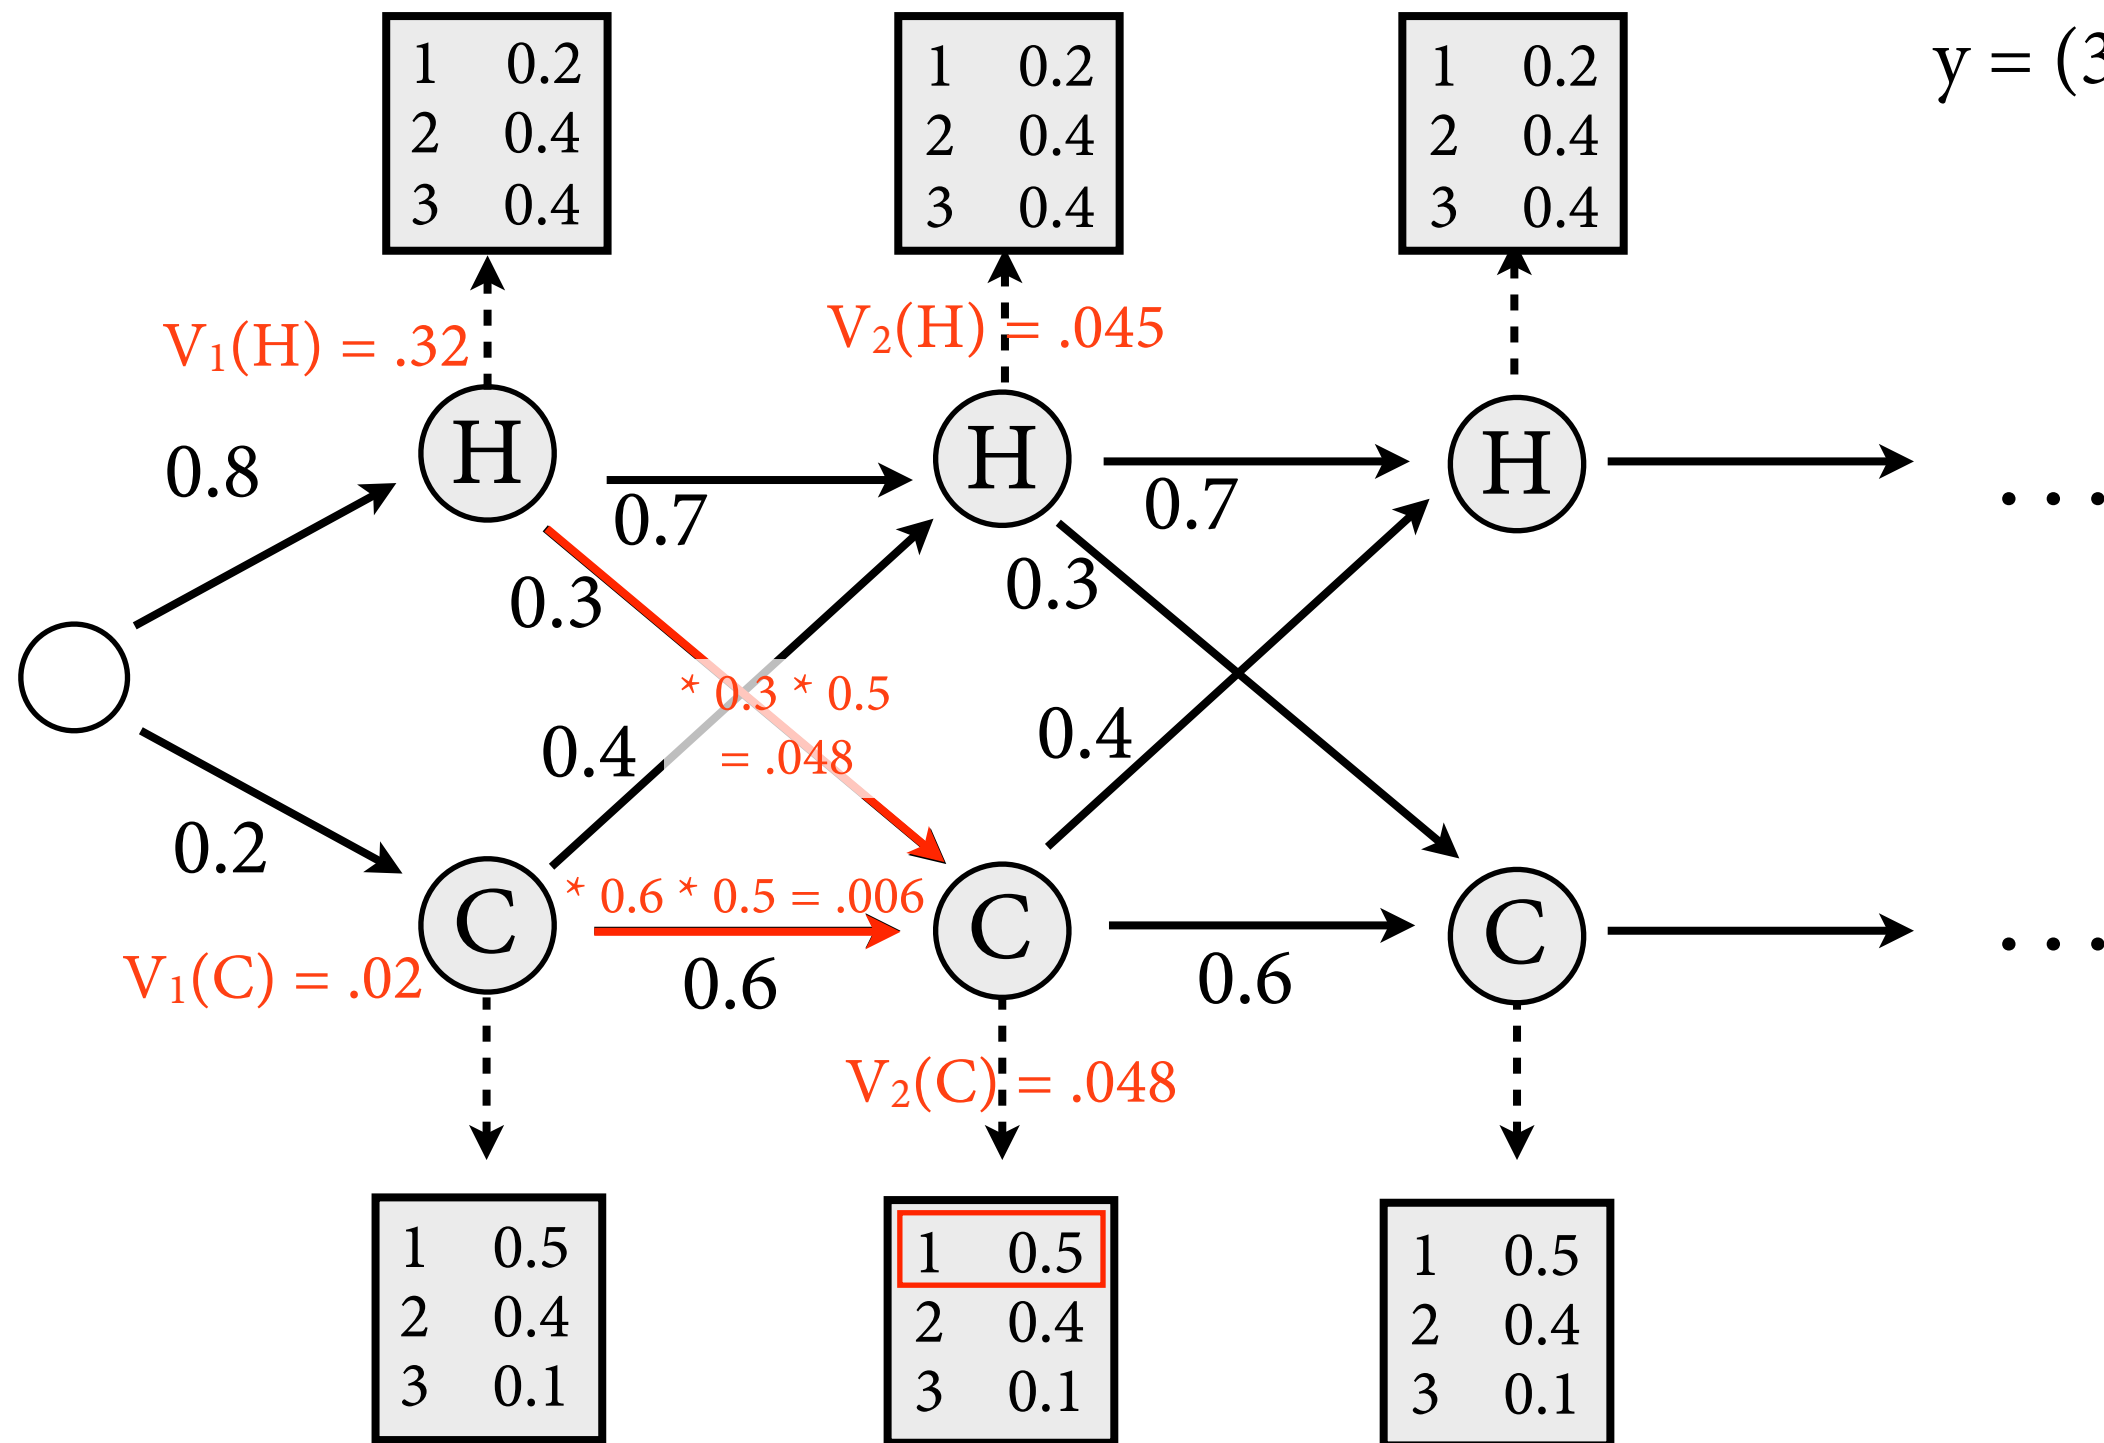

$y = (3,1,3)$

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

Computing best path probs

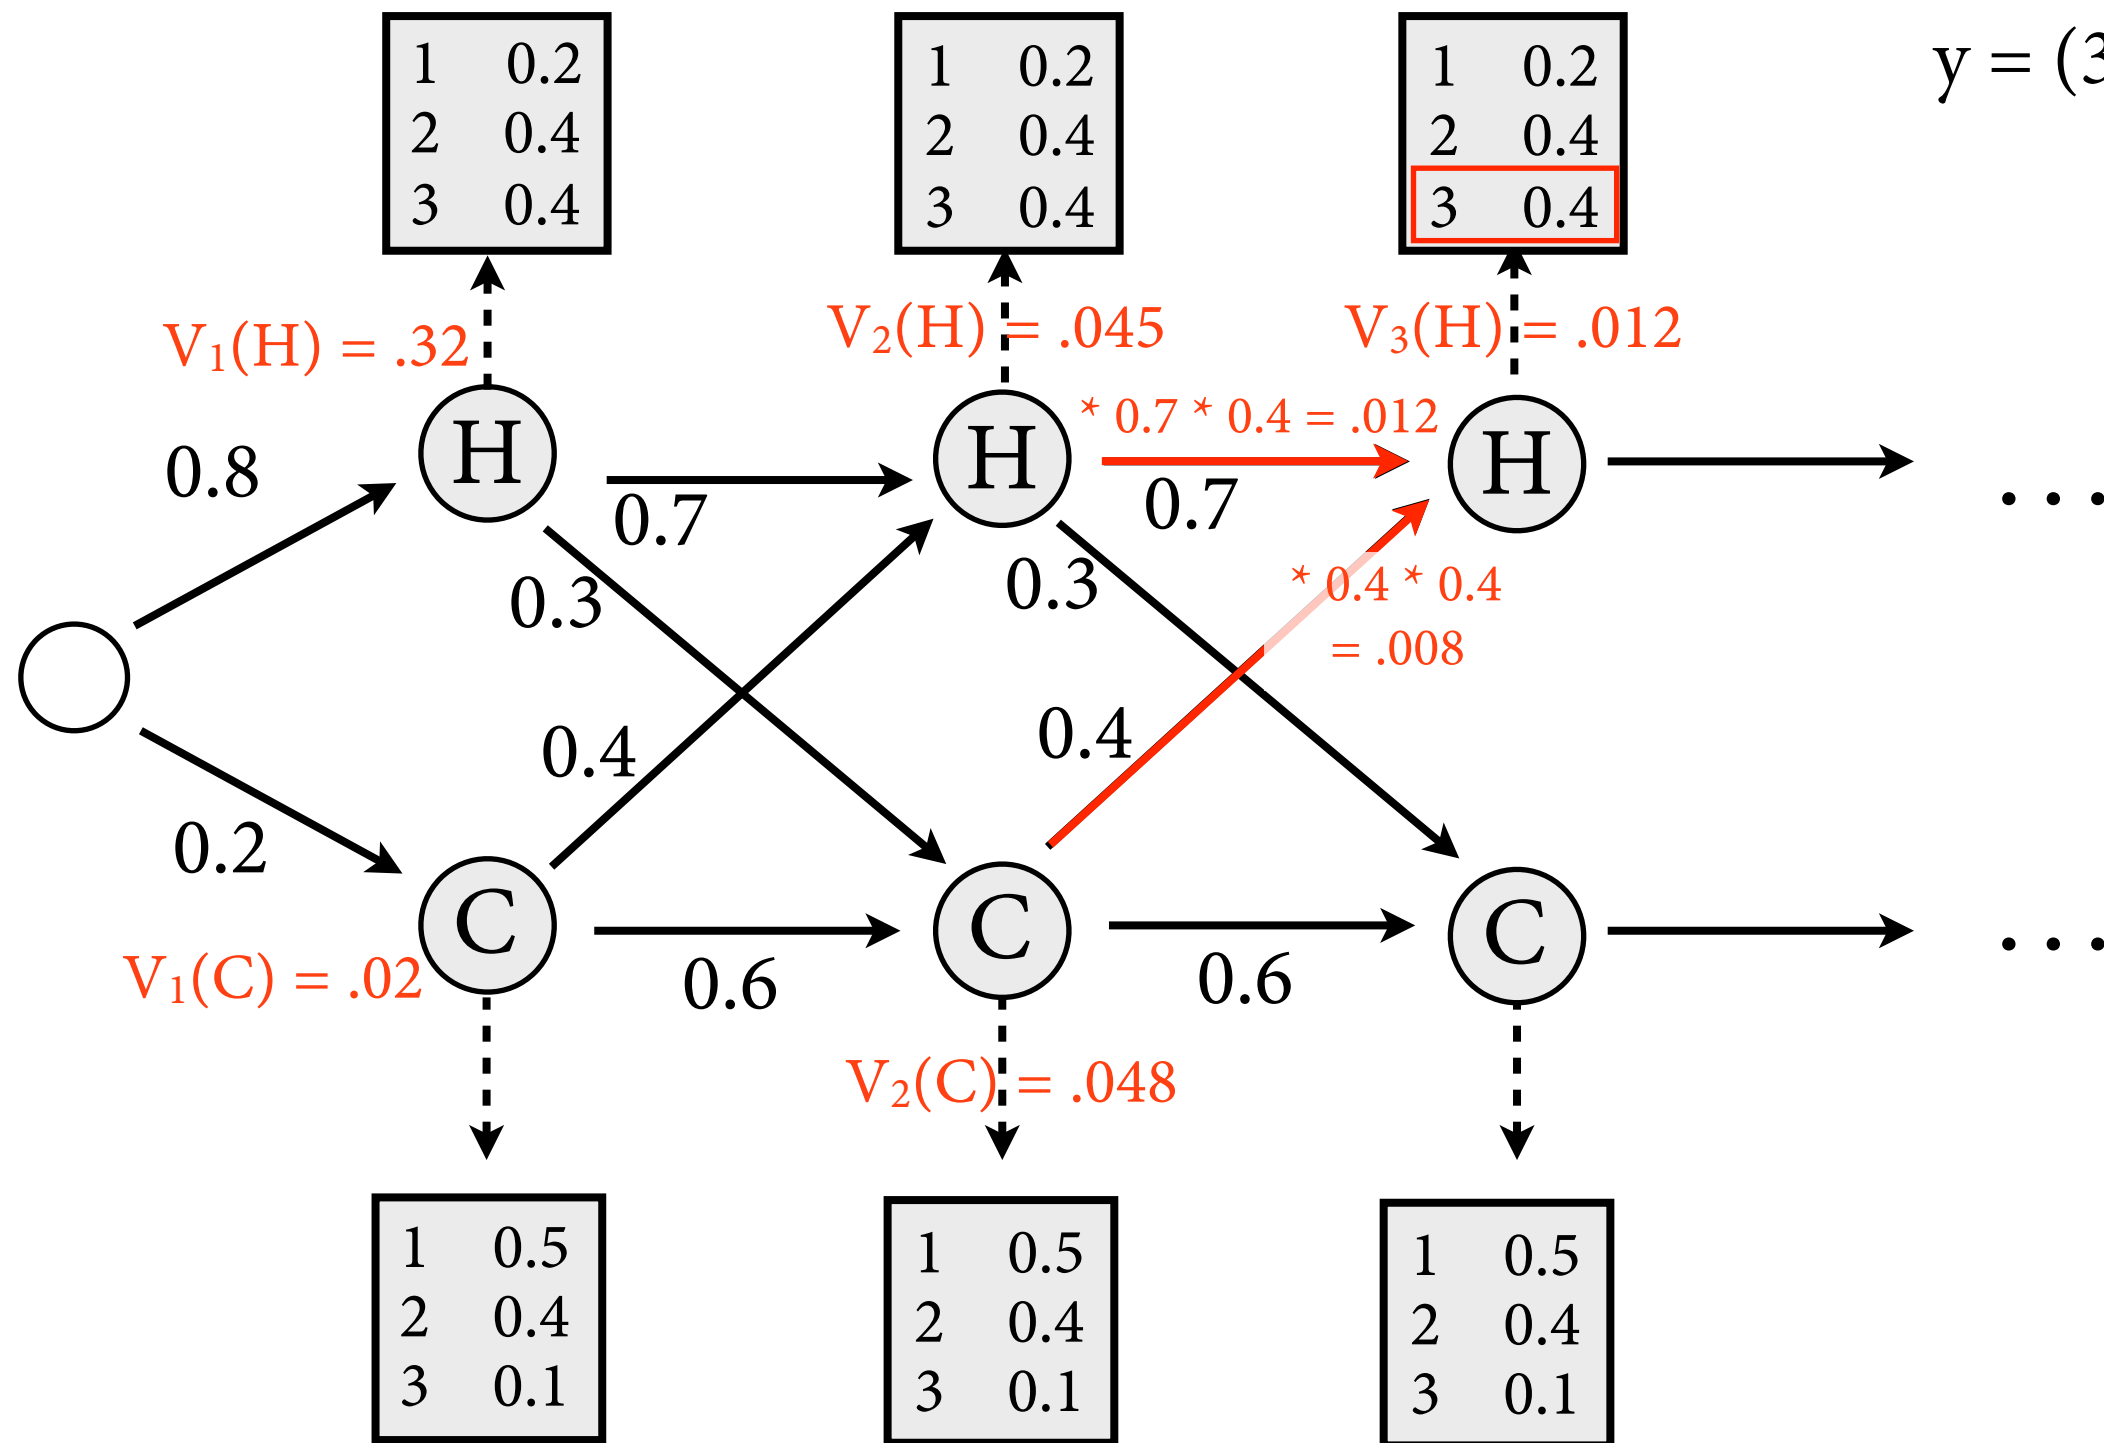

$y = (3,1,3)$

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

Computing best path probs

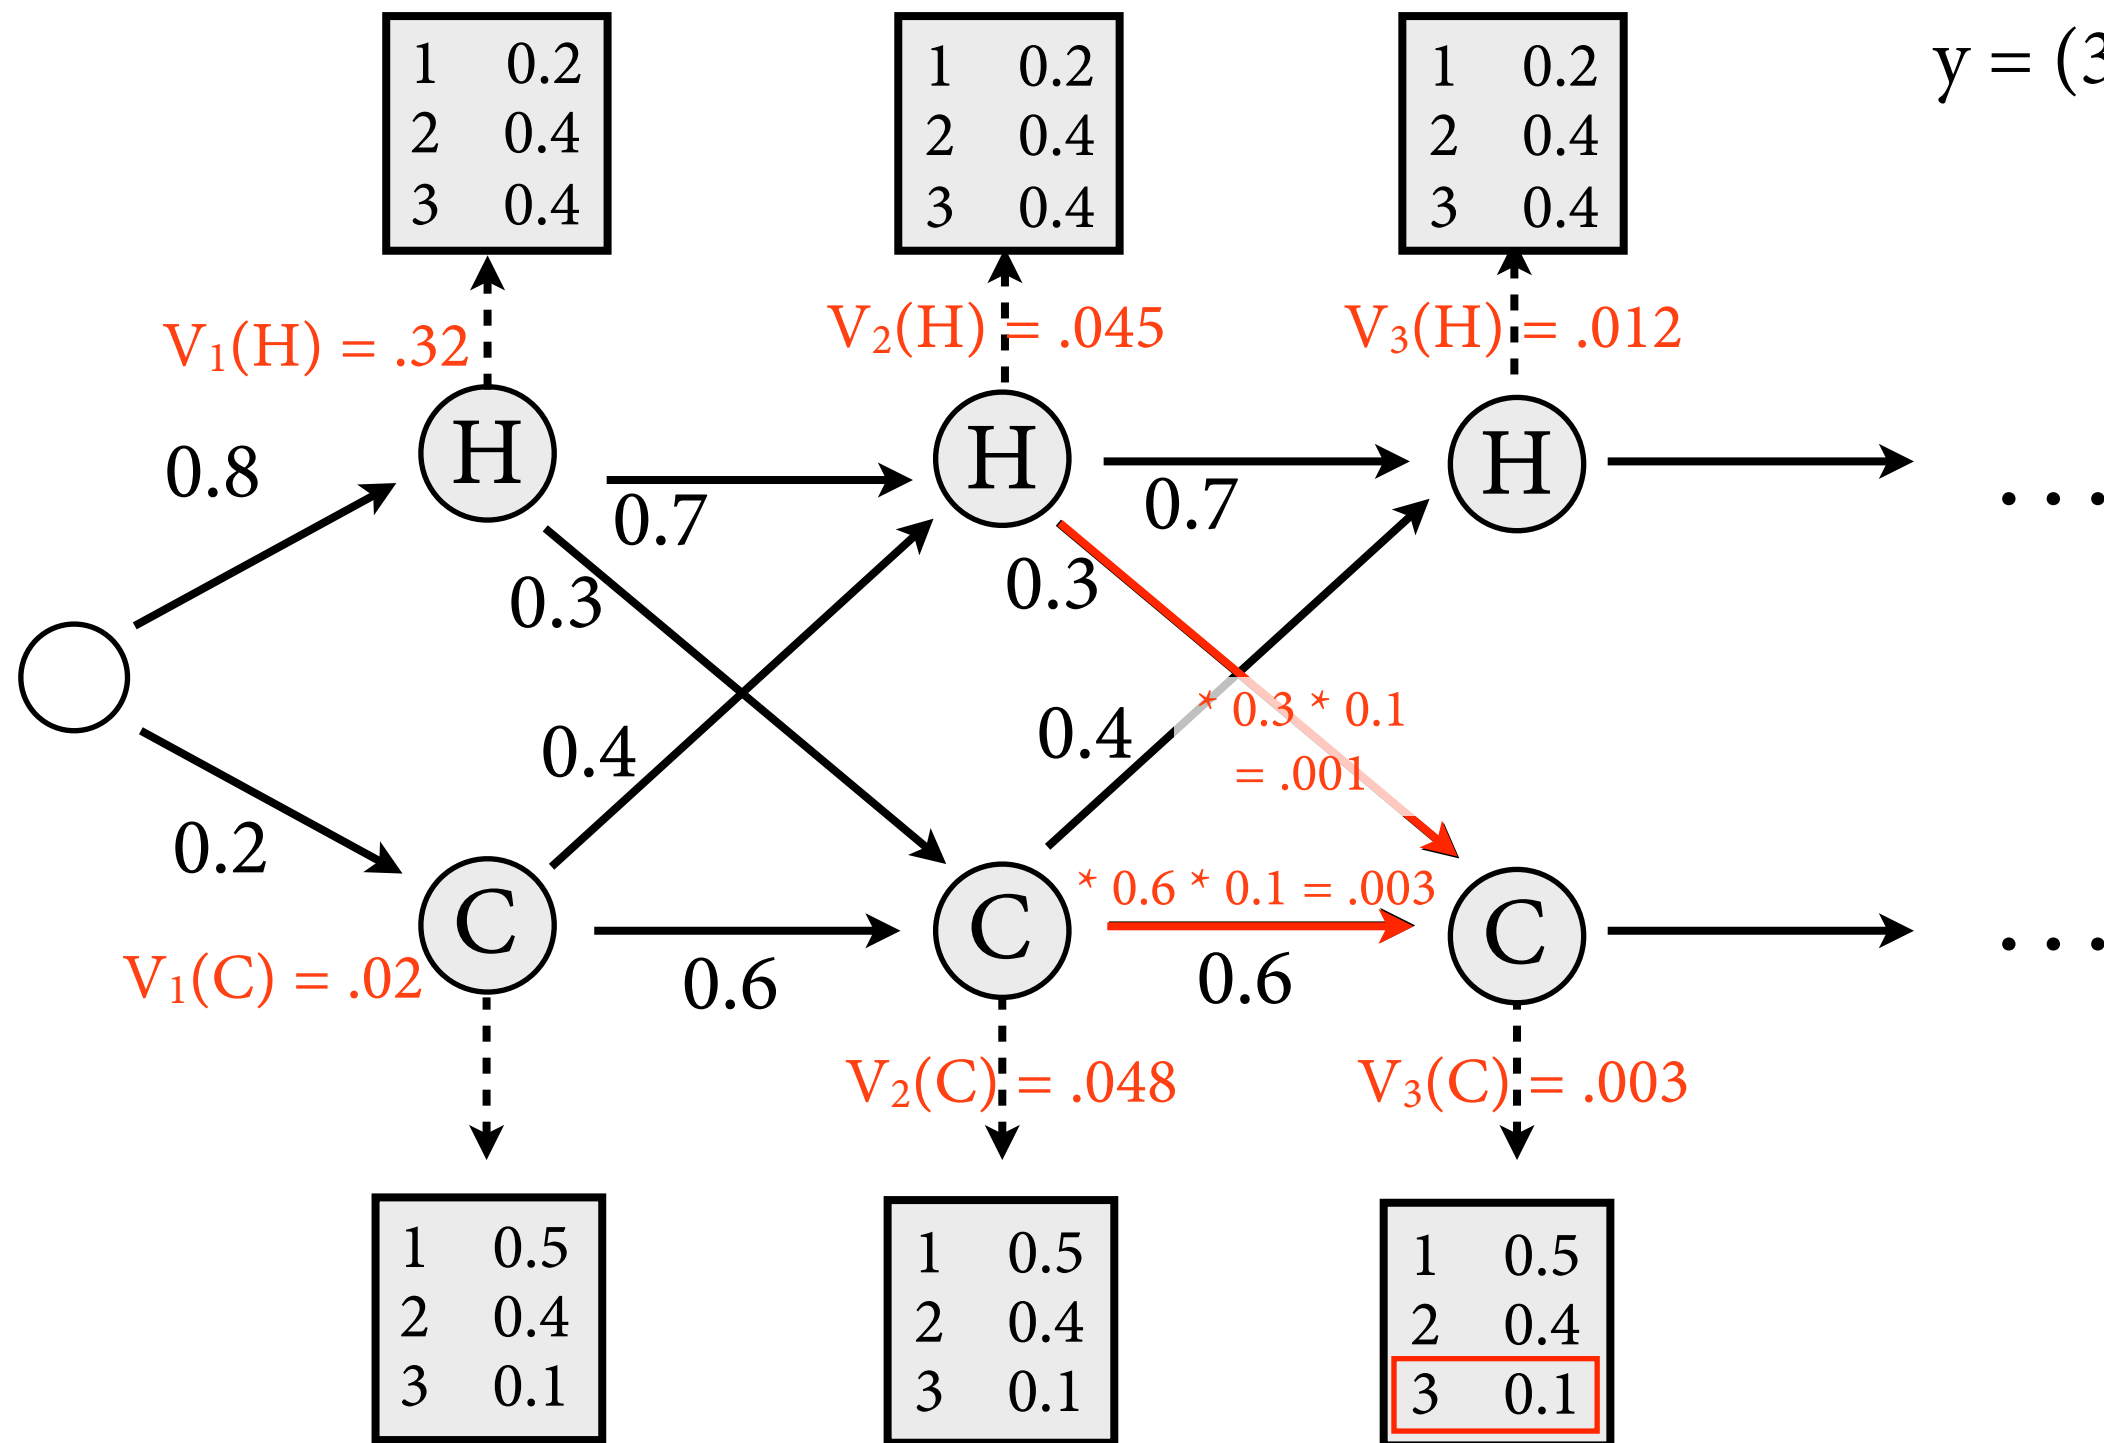

$y = (3,1,3)$

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

Computing best path probs

$y = (3,1,3)$

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

The Viterbi Algorithm

- Because of statistical independencies, can decompose joint probability:

$$\begin{aligned} P(x_1, y_1, \dots, x_t, y_t) &= P(y_t \mid x_1, \dots, x_t, y_1, \dots, y_{t-1}) \cdot P(x_t \mid x_1, \dots, x_{t-1}, y_1, \dots, y_{t-1}) \\ &\quad \cdot P(x_1, y_1, \dots, x_{t-1}, y_{t-1}) \\ &= P(y_t \mid x_t) \cdot P(x_t \mid x_{t-1}) \cdot P(x_1, y_1, \dots, x_{t-1}, y_{t-1}) \end{aligned}$$

- Thus, maximum has recursive structure:

$$\begin{aligned} V_t(j) &= \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j) \\ &= \max_{x_1, \dots, x_{t-1}} P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid x_{t-1}) \cdot P(y_1, \dots, y_{t-1}, x_1, \dots, x_{t-1}) \\ &= \max_{x_{t-1}} P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid x_{t-1}) \cdot \left(\max_{x_1, \dots, x_{t-2}} P(y_1, \dots, y_{t-1}, x_1, \dots, x_{t-1}) \right) \\ &= \max_i P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid X_{t-1} = q_i) \cdot \left(\max_{x_1, \dots, x_{t-2}} P(y_1, \dots, y_{t-1}, x_1, \dots, X_{t-1} = q_i) \right) \\ &= \max_i P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid X_{t-1} = q_i) \cdot V_{t-1}(i) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t) \end{aligned}$$

The Viterbi Algorithm

- Because of statistical independencies, can decompose joint probability:

$$\begin{aligned} P(x_1, y_1, \dots, x_t, y_t) &= P(y_t \mid x_1, \dots, x_t, y_1, \dots, y_{t-1}) \cdot P(x_t \mid x_1, \dots, x_{t-1}, y_1, \dots, y_{t-1}) \\ &\quad \cdot P(x_1, y_1, \dots, x_{t-1}, y_{t-1}) \\ &= P(y_t \mid x_t) \cdot P(x_t \mid x_{t-1}) \cdot P(x_1, y_1, \dots, x_{t-1}, y_{t-1}) \end{aligned}$$

- Thus, maximum has recursive structure:

$$\begin{aligned} V_t(j) &= \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j) \\ &= \max_{x_1, \dots, x_{t-1}} P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid x_{t-1}) \cdot P(y_1, \dots, y_{t-1}, x_1, \dots, x_{t-1}) \\ &= \max_{x_{t-1}} P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid x_{t-1}) \cdot \left(\max_{x_1, \dots, x_{t-2}} P(y_1, \dots, y_{t-1}, x_1, \dots, x_{t-1}) \right) \\ &= \max_i P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid X_{t-1} = q_i) \cdot \left(\max_{x_1, \dots, x_{t-2}} P(y_1, \dots, y_{t-1}, x_1, \dots, X_{t-1} = q_i) \right) \\ &= \max_i P(y_t \mid X_t = q_j) \cdot P(X_t = q_j \mid X_{t-1} = q_i) \cdot V_{t-1}(i) \end{aligned}$$

$= \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$

The Viterbi Algorithm

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

- Base case, $t = 1$:

$$V_1(j) = P(y_1, X_1 = q_j) = b_j(y_1) \cdot c_j$$

- Inductive case, for $t = 2, \dots, T$:

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

- Once we have calculated all V values, we can easily calculate prob of best path:

$$\max_{x_1, \dots, x_T} P(x_1, y_1, \dots, x_T, y_T) = \max_{q \in Q} V_T(q)$$

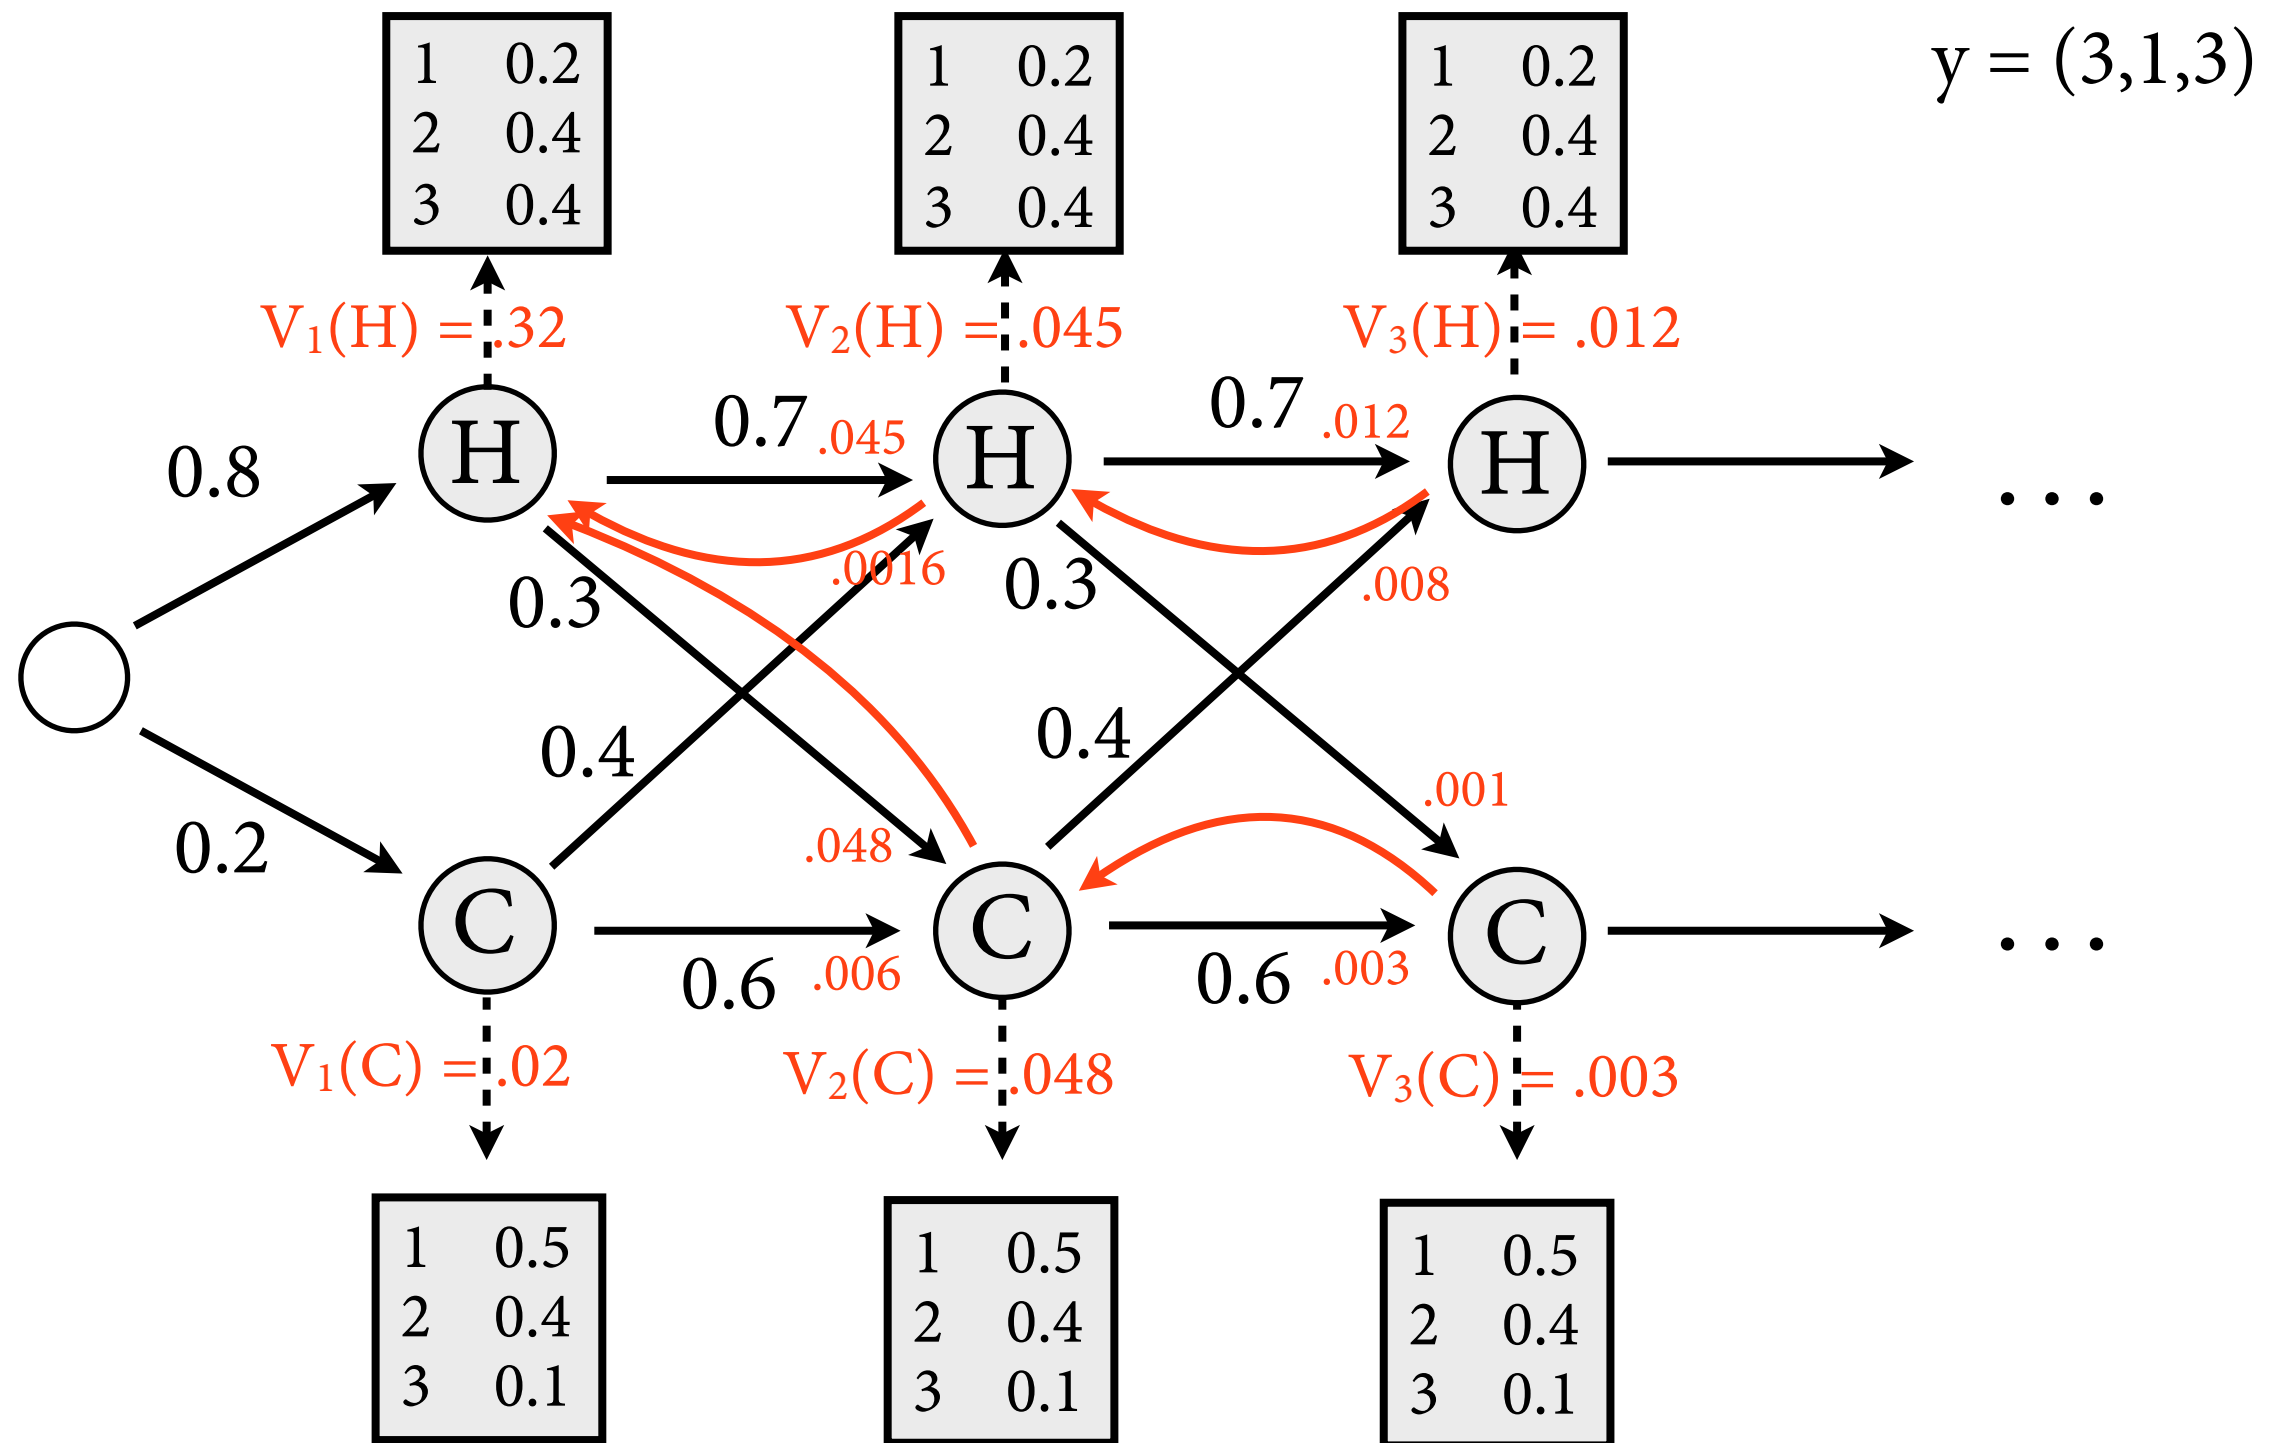

Backpointers

- In the end, we need to reconstruct the sequence of states x_1, \dots, x_T with max probability.
- For each t, j : remember the value of i for which the maximum was achieved in *backpointer* $bp_t(j)$.

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

- Then just follow backpointers from right to left.

Viterbi Algorithm: Example

$$V_t(j) = \max_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, x_1, \dots, x_{t-1}, X_t = q_j)$$

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

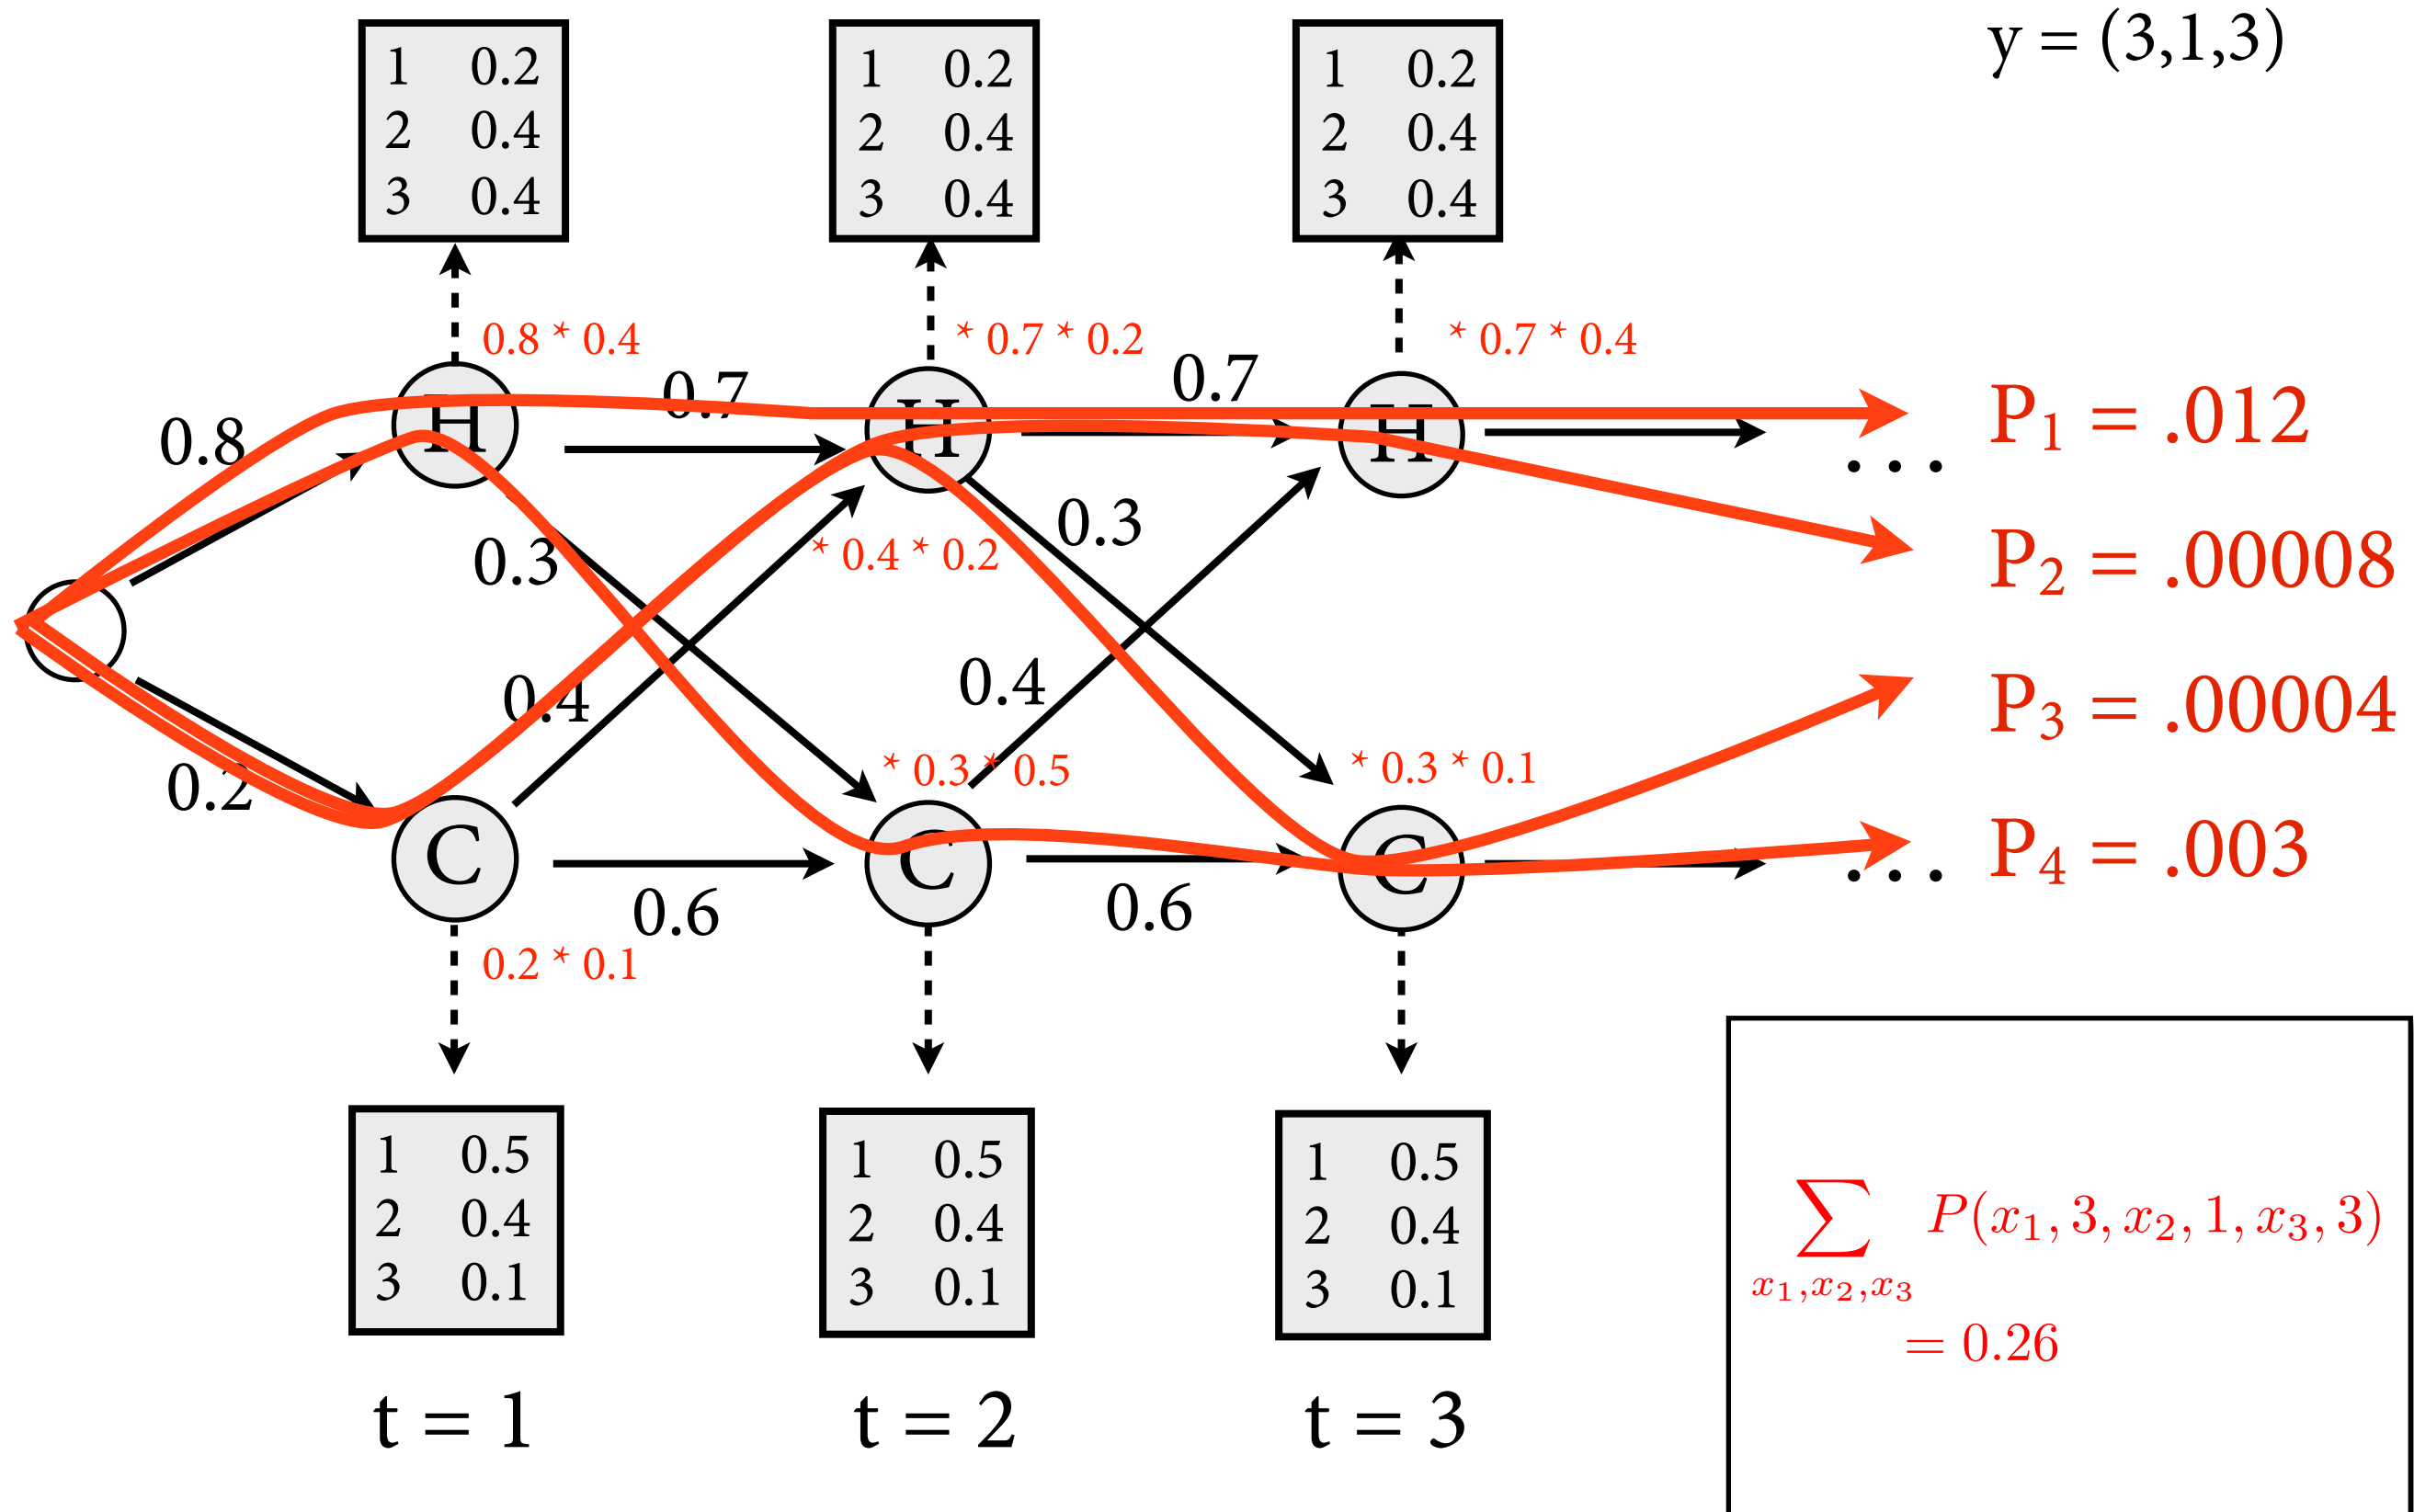

Question 1: Likelihood, $P(y)$

- How likely is it that Jason Eisner ate 3 ice creams on day 1, 1 ice cream on day 2, 3 ice creams on day 3?
- Want to compute: $P(3, 1, 3)$.
- Same problem as with max:
 - ▶ Output 3, 1, 3 can be emitted by many different state sequences.
 - ▶ Obtain by marginalization:

$$P(3, 1, 3) = \sum_{x_1, x_2, x_3 \in Q} P(x_1, 3, x_2, 1, x_3, 3)$$

- ▶ Naive computation is far too slow.

Ice cream trellis

The Forward Algorithm

- Key idea: *Forward probability* $\alpha_t(j)$ that HMM outputs y_1, \dots, y_t and then ends in $X_t = q_j$.

$$\begin{aligned}\alpha_t(j) &= P(y_1, \dots, y_t, X_t = q_j) \\ &= \sum_{x_1, \dots, x_{t-1}} P(y_1, \dots, y_t, X_1 = x_1, \dots, X_{t-1} = x_{t-1}, X_t = q_j)\end{aligned}$$

- From this, can compute easily

$$P(y_1, \dots, y_T) = \sum_{q \in Q} \alpha_T(q)$$

The Forward Algorithm

$$\alpha_t(j) = P(y_1, \dots, y_t, X_t = q_j)$$

- Base case, $t = 1$:

$$\alpha_1(j) = P(y_1, X_1 = q_j) = b_j(y_1) \cdot c_j$$

- Inductive case, compute for $t = 2, \dots, T$:

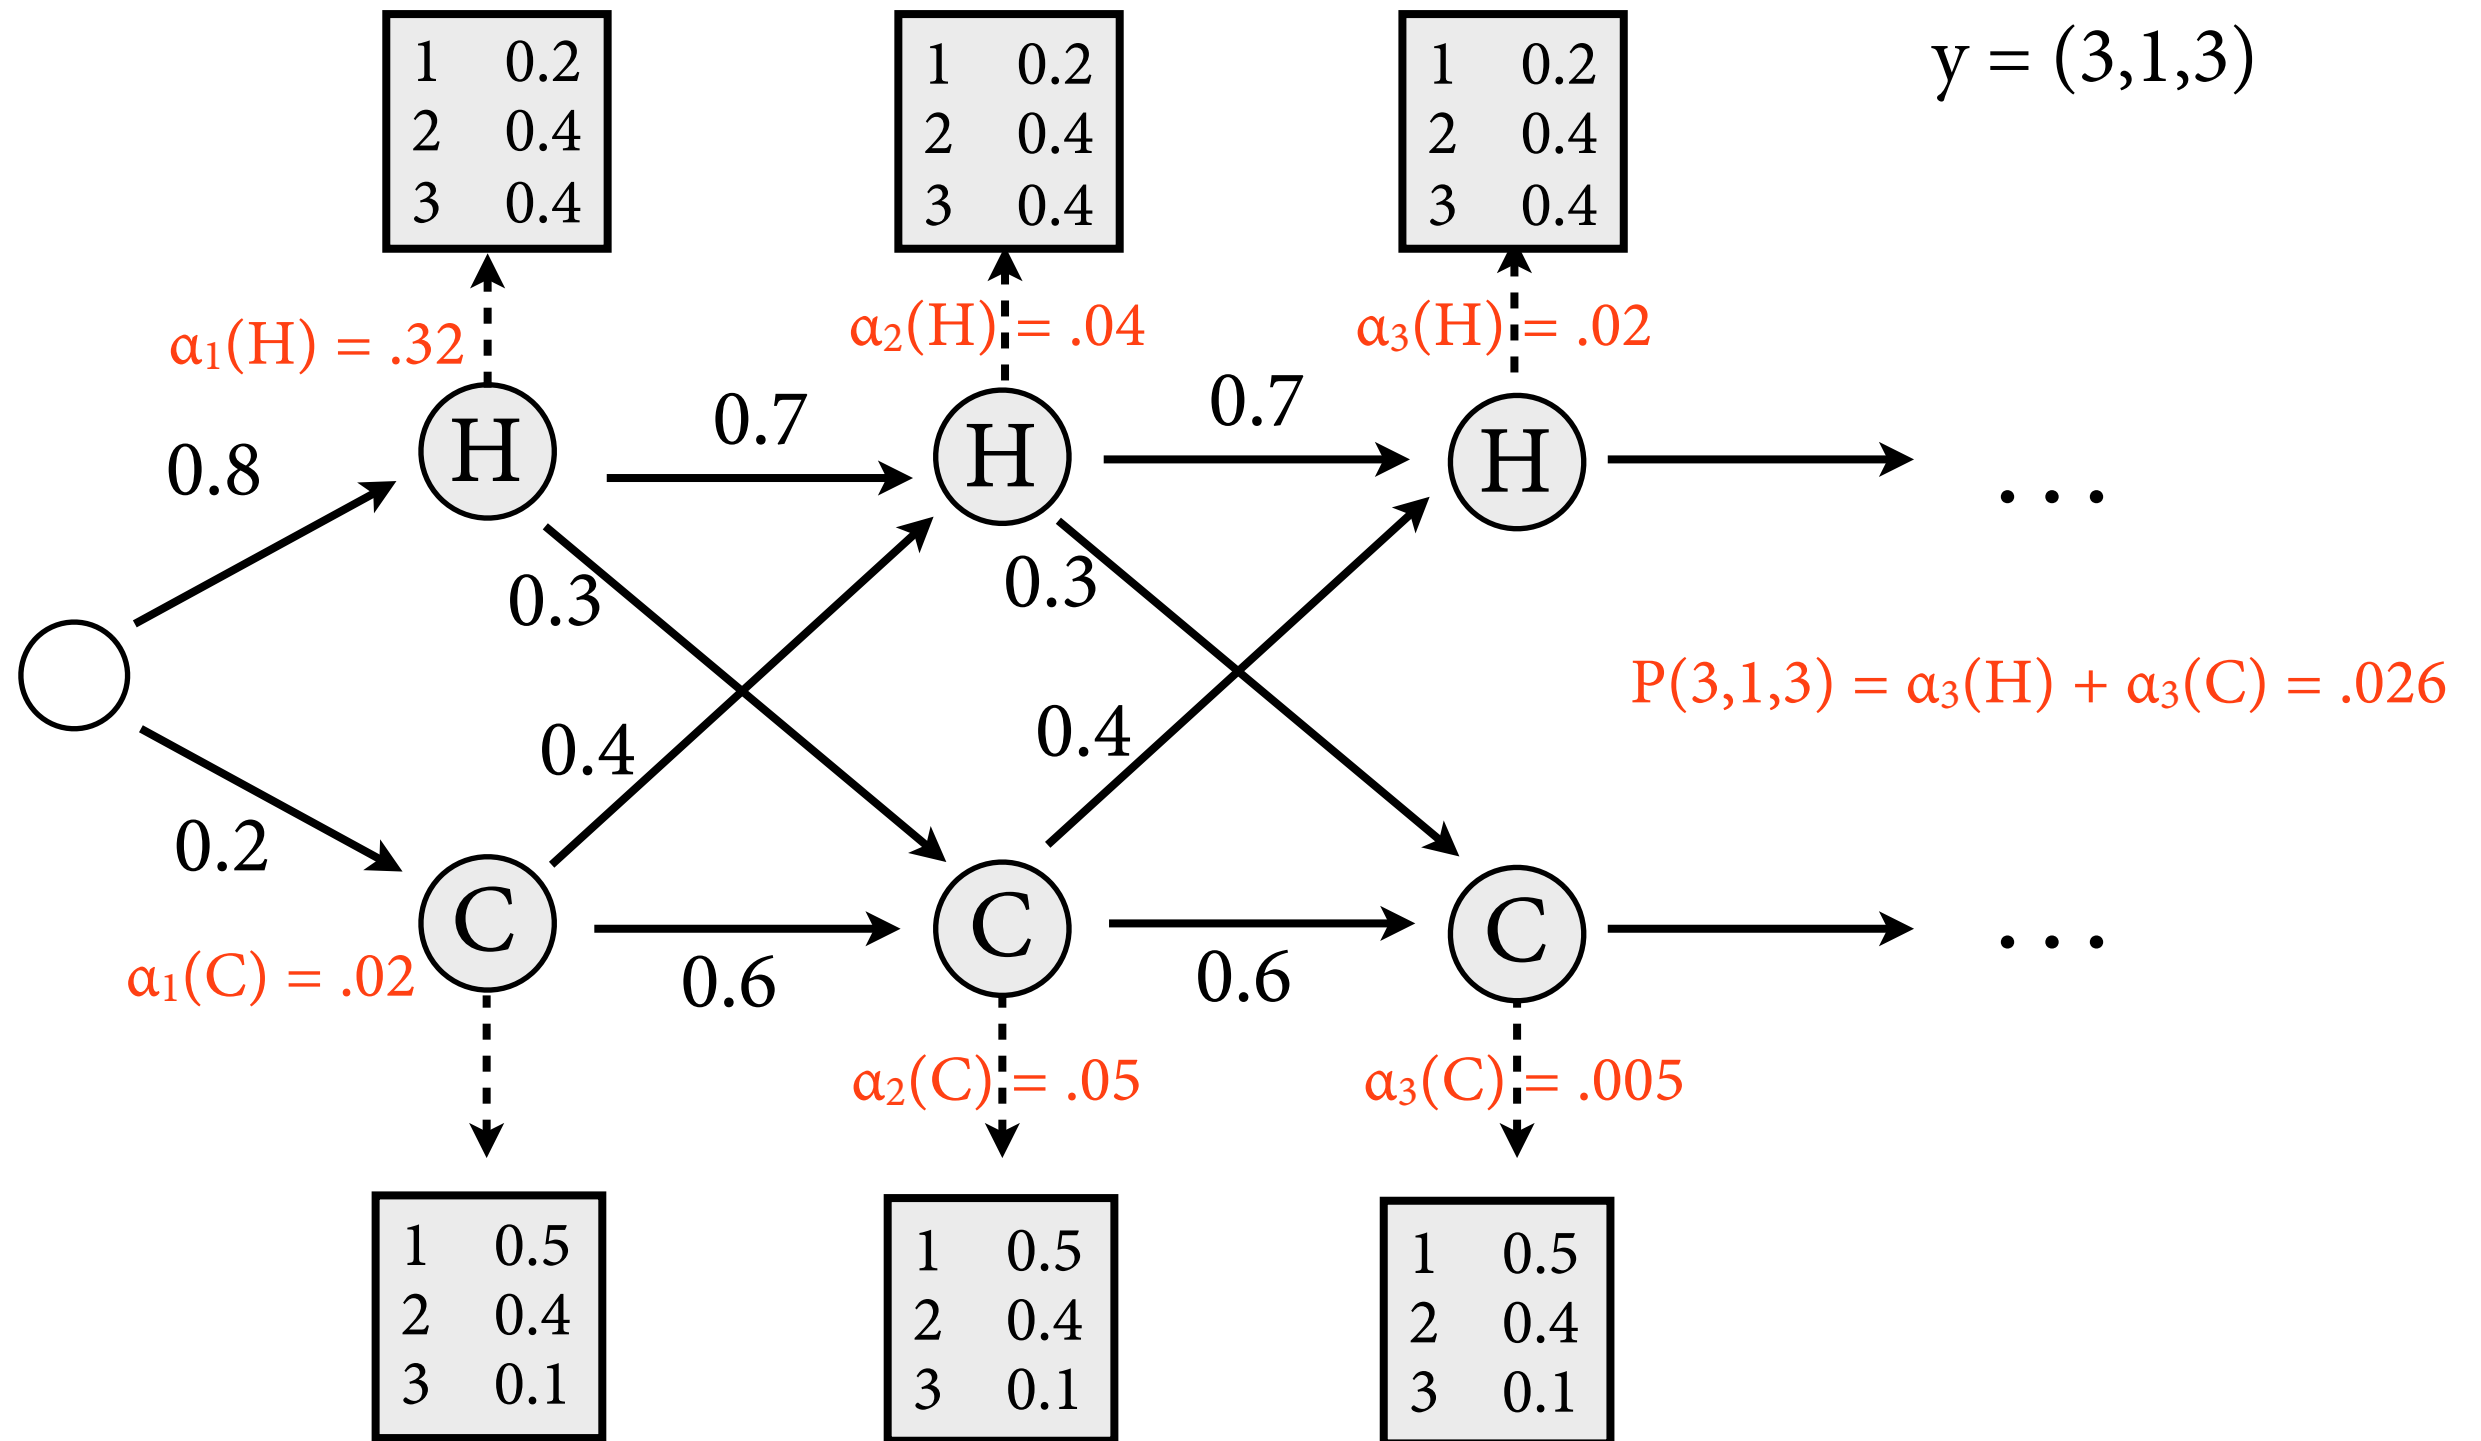

$$\alpha_t(j) = P(y_1, \dots, y_t, X_t = q_j)$$

$$= \sum_{i=1}^N P(y_1, \dots, y_{t-1}, X_{t-1} = q_i) \cdot P(X_t = q_j \mid X_{t-1} = q_i) \cdot P(y_t \mid X_t = q_j)$$

$$= \sum_{i=1}^N \alpha_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

P(3,1,3) with Forward

$$\alpha_t(j) = P(y_1, \dots, y_t, X_t = q_j)$$

$$\alpha_1(j) = b_j(y_1) \cdot a_{0j}$$

$$\alpha_t(j) = \sum_{i=1}^N \alpha_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

Runtime

- Forward and Viterbi have the same runtime, dominated by inductive step:

$$V_t(j) = \max_{i=1}^N V_{t-1}(i) \cdot a_{ij} \cdot b_j(y_t)$$

- Compute $N \cdot T$ values for $V_t(j)$. Each computation step requires iteration over N predecessor states.
- Total runtime is $O(N^2 \cdot T)$, i.e.
 - ▶ linear in sentence length
 - ▶ quadratic in size of tag set

Summary

- Hidden Markov Models popular model for POS tagging (and other applications, see later).
- Two coupled random processes:
 - ▶ bigram model for hidden states (“Markov Chain”)
 - ▶ model for producing observable output from each state
- Efficient algorithms for common problems:
 - ▶ Likelihood computation: Forward algorithm
 - ▶ Best state sequence: Viterbi algorithm.
